Guaranteed Gearing

ROBERT ADAMS,

65 & 67, Newington Causeway, LONDON, S.E.

The Originator and Leading Maker of the Modern System of Ventilating Gearing.

HIGHEST AWARDS AT PARIS, 1900.

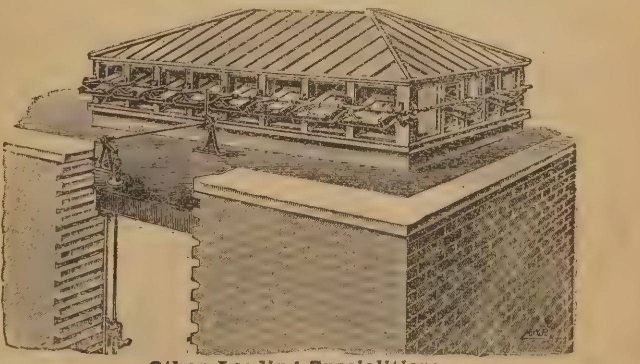
"ADAMS' SPECIAL CONTINUOUS GEARING"

used in most of the best known Public Buildings in the United Kingdom.

ILLUSTRATED PRICE LISTS ON APPLICATION.

FIFTEEN GOLD MEDALS AWARDED.

This Illustration shows the Gearing fixed outside, the Controlling Handle being within the Room.



Other Leading Specialities:

THE "VICTOR" SILENT DOOR SPRINGS
(Oil or Pneumatic Check Action).

FANLIGHT OPENERS. New Patterns.

PANIC-EGRESS BOLTS. Approved by the L.C.C.

New Companies.

Bayton Coal, Coke and Brick Colliery Co., Ltd.

Registered to acquire from W. L. Viggars his interest in certain lands, mines and minerals at Bayton, Worcestershire; and to carry on the business of colliery and mine owners, makers of clay, brick-earth, bricks, tiles, pipes, &c. Capital 2,000 in £1 shares. The first directors are E. H. Eardley, W. R. Berrington, R. C. L. Roberts and W. L. Viggars. Registered office: High Street, Cleobury Mortimer, Salop.

Barnett & Sons, Ltd.

Registered to acquire the business carried on by S. Barnett, as S. Barnett & Sons, at the Rattlechain and New Stour Valley Brickworks, Dudley Port, Rowley Regis, brick and tile manufacturers. Capital £20,000 in £1 shares. The first directors are S. Barnett (chairman), W. Barnett and J. Barnett. Registered office: Tividale, near Dudley Port, Rowley Regis, Staffordshire.

M. H. Blanchard & Co., Ltd.

Registered to acquire the business of terra-cotta, brick, tile and earthenware pipe manufacturer, lime burner and merchant, now carried on at Bishop's Waltham, in the county of Southampton, by M. H. Blanchard, as M. H. Blanchard & Co.; and to carry on the business of builders, contractors, dealers in building materials, &c. Capital £20,000 in £1 shares. The first directors are M. H. Blanchard, A. H. Bone and W. Cowley. Registered Office: Bishop's Waltham, Hants.

Drew-Bear, Perks & Co., Ltd.

Registered to enter into an agreement with T. Drew-Bear, E. H. Perks and A. J. Greig for the acquisition of the business of Drew-Bear, Perks & Co., and to carry on the business of ironfounders, mechanical engineers, tool makers, brassfounders, metal workers, &c. Capital £100,000 in £5 shares (9,800 preferred). The first directors are T. Drew-Bear (chairman and managing director), E. H. Perks and A. I. Greig. Registered office: 71A, Queen Victoria Street, E.C.

Keystone Incandescent Co., Ltd.

Registered with a capital of £100,000 in £1 shares.

Kinnaird Park Estate Co., Ltd.

Registered to acquire all or part of the Kinnaird Park Estate, Bromley, Kent, and to carry on the business of land and property owners and dealers, builders, contractors, farmers, graziers, &c. Capital £40,000 in £10 shares. The first directors are G. Loby, C. Savage, W. G. Allen, H. G. Norris, E. T. D. Wilson and W. Prebble (managing director). Registered office: 4, Walbrook, E.C.

Robertsbridge Brick Co., Ltd.

Registered to carry on the business of brick, tile, pipe, pottery, earthenware, terra-cotta, china and ceramic-ware manufacturers, paviors, dealers in artificial stone, &c. Capital £1,000 in £1 shares. Registered office: Messrs. Murgess & Co.'s corn stores, Robertsbridge, Sussex.

Smith & Pearson, Ltd.

Registered for the purpose of acquiring the goodwill of the Irish business of iron fence, gate and railing manufacturers, now carried on by Messrs. Henry Smith & Joseph H. Smith, under the style of Hill & Smith, at 47, Dawson Street, Dublin. Capital £8,000, divided into 8,000 £1 shares. The first directors are Messrs. John B. Pearson, Joseph Henry Smith, and Charles Frederic Allen. Registered office: 47, Dawson Street, Dublin.

Stanley Land and Brick Co., Ltd.

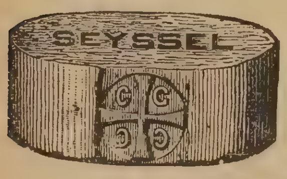
Registered primarily to acquire as a going concern the business heretofore carried on by the Stanley Land and Brick Co., Ltd. (registered in 1880); to grant building, occupation or other leases; to lay-out land for building purposes; as manufacturers of and dealers in bricks, tiles, pipes, pottery, concrete, flags, pavements, timber, limestones, slates, coal, metals; as estate brokers, builders and contractors, and builders' merchants. Capital £100,000 in £5 shares. The first directors are S. H. Holme, J. Wethered, C. G. Jackson and W. P. Wethered.

Victoria Mansions, Ltd.

Registered to adopt an agreement with C. H Wilson, M.P., and to provide, furnish, equip and control lodging-houses, &c. Capital £30,000 in £10 shares.

Wigan Estates Co., Ltd.

Registered with a capital of £10,010 in £5 shares.



W. SALTER & CO.,

SEYSSEL AND LAVA ASPHALTES.

Horizontal and Vertical damp course; flat roofs, basement, and other floors, &c.; or any other Asphalting work. All communications to—

480, HARROW ROAD, PADDINGTON, W.

ESTABLISHED 1870.

WILLESDEN PAPER

2 PLY. FOR ALL CLIMATES. 1 PLY.

For UNDERLINING SLATES, TILES, IRON BUILDINGS, with or without Boards. For LAYING ON JOISTS.
PLACED UNDER FLOOR BOARDS EXCLUDES DAMP, DUST, AND DEADENS SOUND. Also for DAMP WALLS.

WILLESDEN PAPER & CANVAS WORKS, Ld., Willesden Junction, N.W.

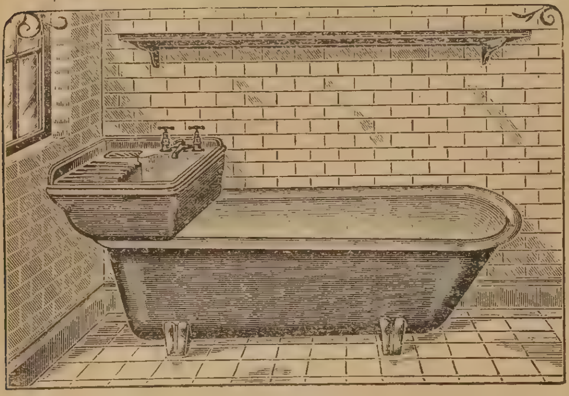
MORRISON & INGRAM'S
. . BATHS. . .



THE PATENT BRAMSTONE COMBINATION BATH & LAVATORY.

The success of the Bramstone combination justifies its introduction, and proves the need for the same.

It is now recognised that no house, however small, should be without bath and lavatory; and since an additional rental is needed of but 2d. per week to yield 5 per cent. on the outlay consequent upon the introduction of the cottage Bramstone Bath, this reform may now be deemed within the reach of all.

It affords economy of space, and a great saving of plumbing is effected.

Only one installation of hot and cold pipes required. It is also made for cold water only. Baths are made 5 ft., 5 ft. 6 in., and 6 ft. long. Prices from £3 11s. 8d. gross.

MAKERS OF ALL KINDS OF BATHS, LAVATORIES, WATER-CLOSETS, URINALS, SINKS, &c., &c.

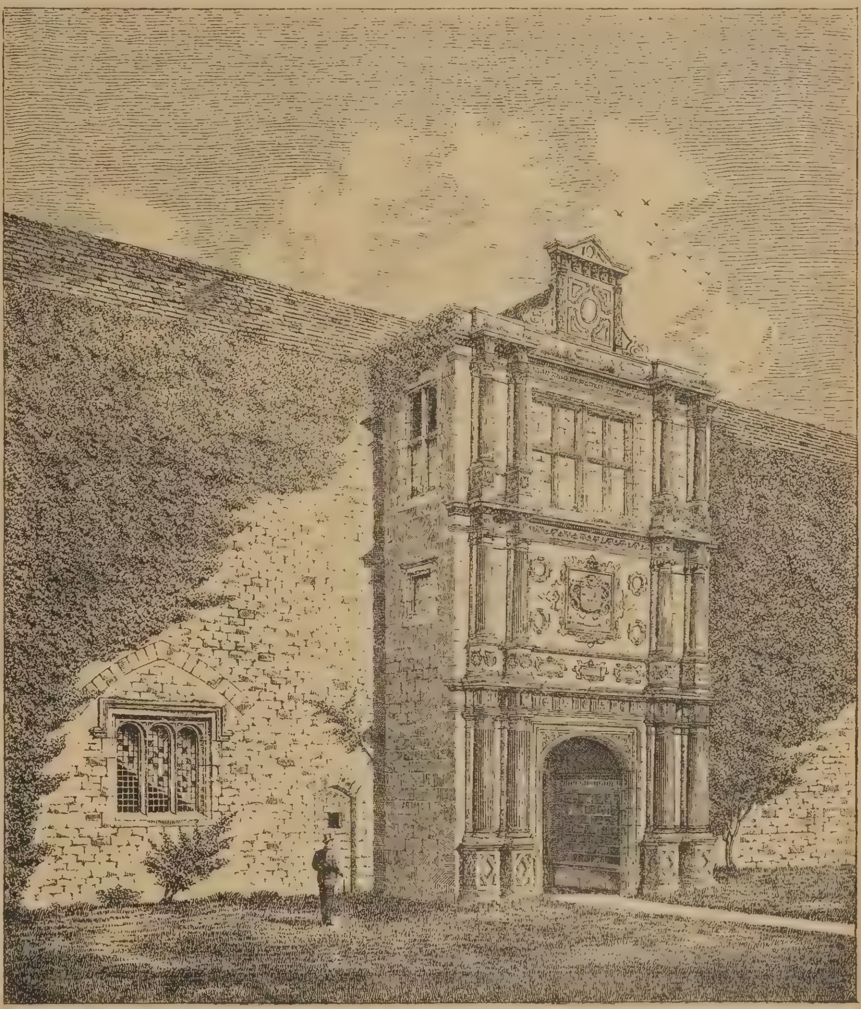
An Architectural Causerie.

Music and Architecture. SUCH a title as this suggests an abstruse dissertation epitomized in the statement that architecture is "frozen music," or, as Goethe would have it, "speechless music." But our purpose is much more practical, since it has reference to the annual conference of the Incorporated Society of Musicians held last week at the Hotel Cecil, and more especially in regard to Dr. Harding's remarks on the effect of musical examinations. This subject furnishes an interesting sidelight on architectural registration. Dr. Harding's contention was that examinations, kept within bounds, were of inestimable benefit, though some had accused them of cramping and stunting the minds and talents of would-be composers. But a real genius would never conform to any set procedure in his studies. No examinations could make or mar a genius, but they could and did materially help to make cultured musicians. If the higher examinations prevented people from composing who had nothing to compose, they should be hailed with delight, for it was generally thought (except by music publishers) that there were too many composers in the present day.—The parallel of architecture will be obvious, though restricted. Music and architecture are produced under such different conditions that they cannot be compared from a single standpoint; and yet there are certain phases of both arts which are analogous. No amount of teaching, however excellent, will make a man a musician if he has not got music in his soul to begin with—an obvious fact, yet one unfortunately unobserved by myriads; and moreover, on the other hand, it is quite possible for a man to be able to compose extempore the most exquisite music and, at the same time, be totally ignorant of the laws of harmony or the theory of counterpoint. Handel and Beethoven might, among many others, be given as instances of the latter fact, but it must be remembered that before they can transcribe their music on to paper they must learn the various theories upon which the notation is based. In the same way, examinations will not make an architect, but they can test the knowledge of construction which he *must* possess to enable him to design, for construction must be the basis of design. Here music and architecture differ. The former deals only with sensuous pleasure, the latter with solid realities. Music affects the ear alone; architecture the eye *and* the intelligence. But in both it is essential to be perfectly familiar with the laws that govern them, the relation of part to part and to the whole; and consequently it is weakness to avoid a test of such knowledge. Every rule has its exception, and maybe genius is exempt from examination; but genius only occurs once in a while; and, with regard to the main body of architects, it is better for the common weal that they should plainly exhibit a thorough knowledge of the use of materials rather than, for fear of shackling the genius, they should be allowed to do as they please.

A Carnegie Library. BY continually exposing every instance of the abuse of competitions, it may be hoped that some good will be effected. Mr. C. H. Reilly draws attention to the most recent. It concerns the first public library to be built under the scheme which Mr. Carnegie's generosity has initiated—that of the small town of Hawick. It appears that the local authorities, having received a grant of £7,000, decided to hold a public competition for the design of the library, and Mr. James Burnet, the well-known president of the Glasgow Institute of Architects, was appointed assessor. Of the designs submitted he chose two, but the Town Council entirely disregarded his decision and, following their own judgment, selected a design by a relative of the town chamberlain. As Mr. Reilly most properly points out, such a barefaced example of nepotism should not be allowed to escape public notice, especially as it concerns a gift which is characterised by its liberality.



ENTRANCE PORCH, OLD BEAUPRÉ, GLAMORGANSHIRE. DRAWN BY W. EATON, A.R.I.B.A.

Entrance Porch, Beaupré, Glamorganshire. BEAUPRÉ MANOR-HOUSE is situated on a beautiful and well-wooded site near the village of Cowbridge, about twelve miles from Cardiff. Originally it was the seat of the Cecil family, who built the greater portion of it, but for many centuries it has been in the possession of the Bassetts. Most of the buildings are in ruins, and the roofs in many instances have fallen in, but the entrance porch is in a very good state of preservation and is well cared for by a farmer who occupies several rooms. The greater portion of the work appears to have been erected about 1586, which is the date on a panel over the entrance doorway to the courtyard, but the Renaissance porch was built later, as stated by the following inscription over its doorway:—Say: Cowldst thov ever fynd or ever heare or see worldly wretche or coward prove a faythfvll frynde to bee. Ry. Charde Bassett, having to wyfe Katherine dovghter to Sir Thomas Johns Knight bwylt this porch with the towers in Ano 1600. His yeres 65. His wife 55.—Gwilt in his encyclopædia, speaking of the style of architecture practised during the reigns of James I. to Anne, says: "The use of the Orders became general. In Glamorganshire at Beaupré Castle (1600), which has a front and porch of the Doric order, we find a composition including that just named the Ionic and the Corinthian wherein the capitals and columns are accurately designed." The accompanying drawing is by Mr. W. Eaton, A.R.I.B.A.

Der Architekt Wilhelm. THE versatile Kaiser fully justifies the title of William the Wonderful. Ruler, soldier, poet, painter, musician, and now—architect. It appears that the authorities at Wiesbaden were erecting new central police offices, the plans for which, after long delay, had been passed by the Minister of the Interior. The foundations were being rapidly completed, when, lo! an order came to stop everything. Four months later operations were resumed, and it now transpires that the reason of this interruption was that the Kaiser had seen the proposed plans, had perceived their imperfections, and had ordered new plans to be made from his own designs! What a splendid P.R.I.B.A. he would make!

LITTLE MORETON HALL.

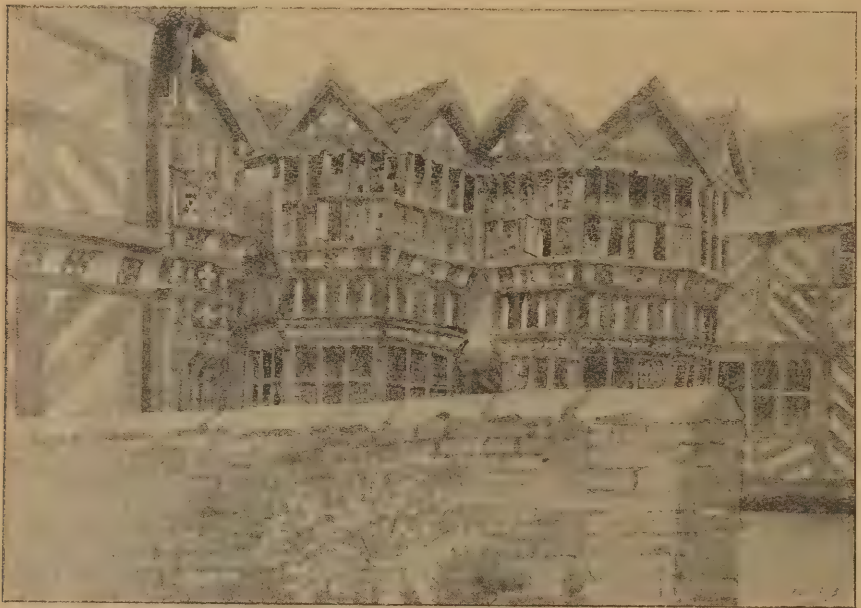
By J. HUTCHINGS, A.R.I.B.A.

ALTHOUGH timber architecture is common in numerous districts of England, the wooden halls of Cheshire and Lancashire belong to a particular school, or at least possess local peculiarities that differentiate them from similar work in other parts of the country.

Examples of the smaller type of house, dating from the sixteenth century downwards, are dotted plentifully over this locality, and exceedingly picturesque and interesting they are. Halls on a larger scale, constructed on the courtyard principle, are naturally far less numerous, and on that account their claims to our interest and study are the greater.

Moreton, though far from the largest in scale, is nevertheless one of the most perfect surviving specimens of the latter class. Situated in Cheshire, near the north-west border of Staffordshire and close to the eminence of Mow Cop, this ancient seat of the Moretons stands in a beautifully wooded portion of the Cheshire plain—even to-day ancestral in its aspect, patrician in its exclusiveness, and still isolated by its moat.

The high road from the North Staffordshire Potteries to Congleton, Macclesfield, and the great manufacturing cities of Lancashire, passes within 200yds. of it, whence comes the stream of sightseers by brake and "bike"; for Moreton, though partly inhabited, is now a great showplace, whose fame is well known in its own and the neighbouring counties.



VIEW IN COURTYARD, ILLUSTRATING SKYLINE.

The hall consists of a number of apartments grouped round a courtyard, completely enclosed except for a gap in the middle of the west side, which affords access to the large kitchen garden, the whole area being surrounded by a moat.

As the buildings are constructed of timber with plaster or brick filling, Moreton could never have been regarded as a fortress, nor, indeed, was there any necessity that it should serve such a purpose in the sixteenth century, to which period the greater portion belongs; and the moat—a survival of some older domicile—must have been retained as an ornamental feature, and possibly as a protection from sudden attack either on the part of a rival landholder or of a band of marauders—no unlikely contingency in those unsettled times. A drawbridge originally occupied the position of the present stone arch, which could be operated at will from the gatehouse by the entrance.

The surrounding dyke would give the dwelling an air of security; and we may be sure that if not raised every night the bridge would be drawn during periods of political unrest and in the absence of the lord of the manor.

The farm buildings stand in an independent enclosure adjoining and without the moat, but these appear of considerably later date than the older portions of the principal structure.

The front range consists of three storeys, the uppermost being the ballroom, a long narrow apartment flanked with a continuous row of windows on each side. This second floor is of considerably less width than the storey below, and presents externally much the same appearance as the clearstory of a church, with the abutting side-aisle roofs. This wing is an imposing architectural conception, well balanced, exellently grouped, beautiful in colour, and direct in construction, but somewhat wanting in simplicity owing to the excessive use of ornament in the panels formed by the main beams.

Within the courtyard fancifulness, picturesqueness and playfulness reign supreme, but combined with an all-pervading air of natural homeliness, such a charming piquant freshness and spontaneity of design, entirely free from the vulgarities perpetrated by the later Jacobean school, that instead of criticizing in a carping utilitarian spirit, the spectator—if, indeed, he possess any leaven of imagination or romance—abandons himself unreservedly to the intoxication of the moment, and drinks in with unchecked delight the remarkable scene that meets his vision; thankfully acknowledging the homely humour and high poetic fervour that endowed the work of the old builders with so much human interest and character. He is at one with these ancient craftsmen, though separated by centuries, and instantly realizes that they were creatures of flesh and blood like himself, endowed with the same emotions, the same love of colour and form, and revelled in quaint tricks and innocent games. They speak to him in many a combination and arrangement of the customs of long ago; they reveal a sturdy common-sense in their solid practical construction; they do not trick him with false veneer, but in absolute fidelity expose mortice and tenon, joint and pin. The materials are the very best that the neighbourhood could furnish—English oak, plaster that has withstood the weather for hundreds of years, and stone roof slabs that promise to outlast the rest of the fabric. And the whole bears evidence of the expenditure of their most utmost skill in resource; and still the carvings whisper fragments of hoary legends; they animate every corner with quaint devices and grotesque suggestions. The hand of the workman appears to have lingered lovingly over every detail, and even Time seems to have dealt in a more relenting mood with this venerable structure than is his wont, hesitating to hurl into formless ruin this beautiful creation, that his own finger has enhanced and adorned.

The entrance porch to the hall and the two large bay windows were added by William Moreton, as the legend carved on the lintels testifies. It reads as follows:—

GOD IS ALL IN ALL THING
THIS WINDOW WHIRE MADE BY WILLIAM
MORETON IN THE YEARE OF OURE LORD MDLIX.
RYCHARDE DALE, CARPEDER, MADE THIES
WINDOWS BY THE GRACE OF GOD.

Richard Dale must have been a craftsman of an extremely high order, judging from the admirable proportions and elegant details of his work. Set upon a basement of stone rising a foot from the ground, the upper storeys of the bays are coved out beyond the lower windows, and the many-gabled roofs are brought still further forward and embellished with barge-boards, enriched beams and carved pendants; the whole having that quaint appearance of top-heaviness so characteristic of old-timber architecture, and which appears so pronounced in the narrow thoroughfares of our older towns. The entrance door has an arched Tudor head, and is flanked with cable pilasters, supporting curious brackets, ornamented with sunk panels and cusps of Gothic design. Above the door are two bands of pilasters, the interstices being filled with painted quatrefoils; above those separated by a plaster cove, also diapered with painted ornament, is a many-mullioned window, the whole surmounted by a gable and projecting barge-board.

This work by Dale, which was added to an older structure, forms a fine composition; it is the most interesting portion of the building, and our respect for the craftsmen of the time must be considerable when we find in an obscure corner of Cheshire a master-carpenter of his knowledge, dexterity and good taste.

The remainder of the courtyard is worthy of study, though treated with greater severity than Dale's addition; but the same fanciful element prevails throughout in a lesser degree, and no portion can be pronounced dull or insipid.

The banqueting hall, occupying the side opposite the main entrance, is a fine apartment, open to the roof, 38ft. long by 28ft. wide. It is partially lighted by one of Richard Dale's bay windows, and the fireplace, reduced in size and shorn of its adornments, is in the wall opposite, whilst the space under the beam in days gone by would be enclosed by a screen to form a disconnecting corridor between the hall on one side and the kitchen and offices on the other. Above was the minstrels' gallery, no longer open at the front, but blocked up with a partition to provide private access to the bedrooms over the kitchen wing. The windows are glazed with leaded glass of good geometrical design, and contain some fragments of stained work, including, among other insignia, a greyhound statant, the crest of the Moreton family. The oak wainscotting was probably added at the time that the bay windows were erected, namely, in 1559. The grand old oak table is a first-rate piece of workmanship, admirably designed and constructed, combining every appearance of strength and durability with elegance of form and propriety of detail.

The lord's parlour and withdrawing-room adjoin the upper, or daïs, end of the hall.

The withdrawing-room is of stately proportions, having a bold ceiling divided into rectilinear compartments by massive beams, deeply moulded. The walls are wainscotted from floor to ceiling, and the heaviness of the ceiling appears in striking contrast to the delicate panelling upon which it appears to rest. Probably the explanation is that the latter also was added by Dale. The original fireplace has been superseded by a tame Georgian design, but the overmantel remains intact and contains the arms of Queen Elizabeth framed by the grotesque pilasters and mouldings of the period.

The lord's private chamber has also been delivered over to the Georgian improver, who is responsible for the sash windows which replace the older mullioned lights.

The kitchen, now opening directly from the hall, is of ample dimensions (in harmony with the hospitable practices of the period), and is provided with an enormous fireplace 11ft. wide. There remains a round table of rude but massive construction, and also a fine oak dresser, equipped with several old pewter vessels bearing the Moreton crest.

The buttery, but little inferior in size to the kitchen, adjoins the latter, and bespeaks a capacity not likely to have been overtaxed even in that age of mighty trenchermen.

The eastern wing contains, besides the curious little chapel with the priest's lodging above, some stable buildings with a suite of bedrooms on the upper storey. The chapel is so extremely small that it must have been intended for private devotions, and probably for occasional Sunday worship when local disorders rendered a journey to the parish church of Astbury unsafe, or during inclement weather, when the badly-tended roads would be practically impassable. A writer thus humorously comments upon this diminutive place of worship: "The ancient sanctuary is of small dimensions, about 12ft. by 9ft., from which it may be assumed that the Moretons, if they required a considerable amount of space for their temporal concerns, were able to manage their spiritual affairs within very moderate limits."

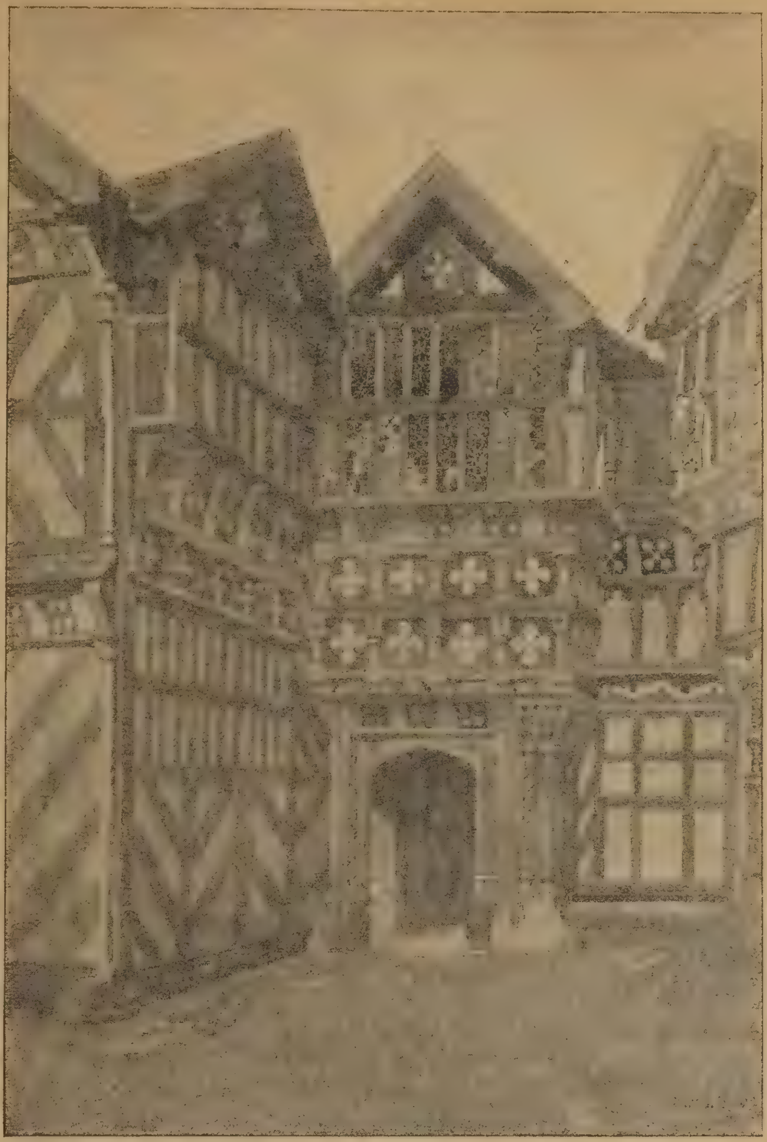
The front range comprises the gateway and a number of stable buildings on the ground floor. The state apartments, containing the garde robes, which empty into the moat—such was the elementary state of sanitary science at the time—occupy the first floor. And in connection with this suite are two secret hiding-places situated in the west wing, and communicating with one of these was a subterranean passage leading beyond the moat.

The top storey is entirely devoted to the ballroom, with the exception of the small retiring room in the gabled projection in the centre of the front.

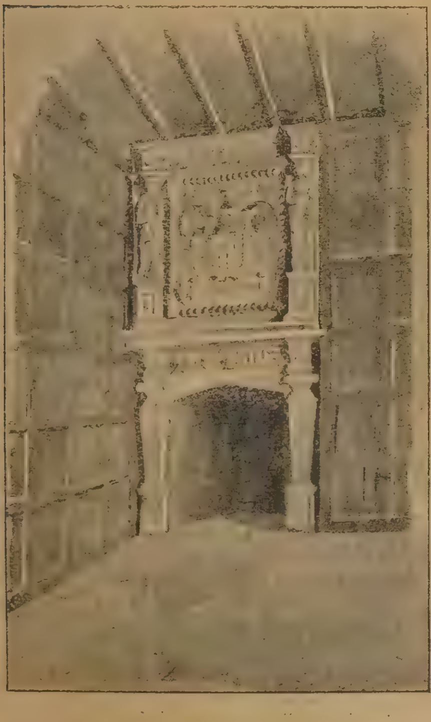
The ballroom is in the form of a gallery 75ft. by 12ft. 6in. wide, lighted on both sides, and now at one end only, the other gable window having been blocked up. The walls are panelled, and the open-timber roof is of good design, embellished with ornamental cross-bracing between the principals and purlins. These proportions, though perfectly adapted to the old-fashioned dances of the Sir Roger de Coverley type, would ill respond to the exigencies of the modern waltz and polka.

There is little documentary history of Moreton, beyond a list of names and matrimonial alliances; but the old walls tell their own tale eloquently enough, and it is evident that the range containing the hall and kitchen existed prior to the middle of the sixteenth century, when William Moreton employed Dale to reconstruct the elevation to the courtyard.

The chapel bears unmistakable evidence of greater antiquity, the ceiling beams having been shaped by an adze, and other details are of the same rude workmanship. The front range was probably erected shortly after the completion of the 1559 additions.



LITTLE MORETON HALL: ENTRANCE.



FIREPLACE IN RETIRING-ROOM ADJOINING BALLROOM.

It therefore appears that the original dwelling consisted of the hall, with the kitchen wing at one end and the withdrawing-room and lord's parlour at the other, the sleeping apartments being above the two wings. The chapel was either a separate building, or was connected with the main block by stables. This was the common plan of an English castle or manor, handed down from remote times; and this group of chambers always formed the nucleus of the more magnificent establishments. The sumptuous state apartments and ballroom would be added either as an outlet for increased wealth or to meet the increasing luxury of the times.

As was usual at the period, each room, with one or two exceptions, occupies the full width of a range, and the chambers are planned opening one out of another, instead of communicating with a landing or corridor, as demanded by the requirements of modern manners.

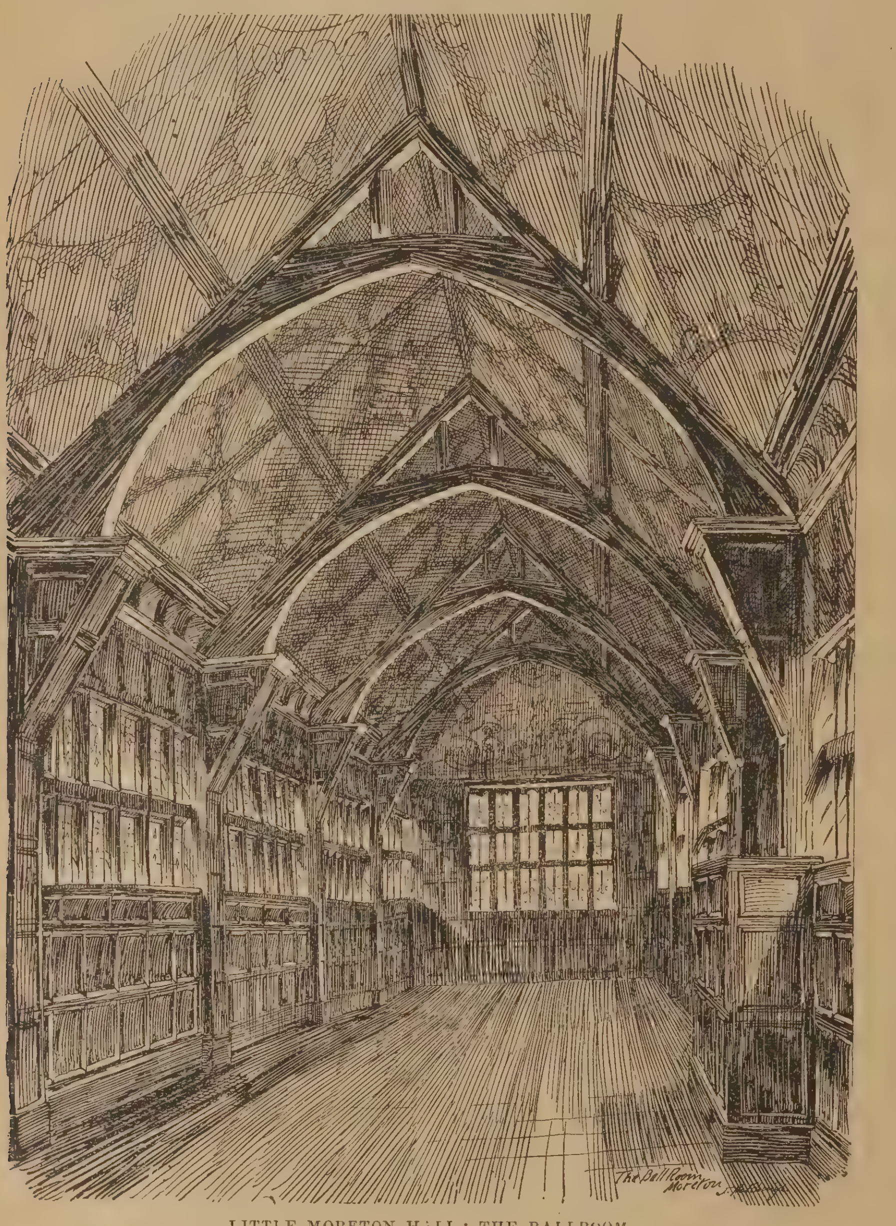
As the Rev. Baring Gould has pointed out, amongst the ancient yeomanry of this country it was quite customary for the master and mistress of a farmhouse to occupy the central bedchamber, the female portion of the household having their quarters on the one side and the males on the other; and as a necessary consequence of this rule the junior members of the family and the servants were obliged to go to bed before their elders and, practically speaking, under their eyes.

Among the many charming features distinguishing old buildings, one of the most delightful is their fitness for the locality. Thus, in the bare Moorland districts grey stone houses appear eminently adapted; the swamps and broads of East Anglia seem the natural home of brick and plaster; whilst in the forest lands of the country with equal propriety sprang up the log hut and timber mansion, wrought in such perfect harmony with their surroundings that they might almost have been raised by Nature's own hand. There is nothing strained or imported about these homes, but construction and ornamentation alike are the outcome of a direct and legitimate application of the means employed. In those days the great cost involved prohibited the transport of materials from a distance, except in exceptional cases, and consequently the building-owner was obliged to content himself with the products of the neighbourhood. Moreover, it was customary, for obvious economic reasons, for the proprietor to obtain a contract from some master-craftsman, who undertook to execute the work, the owner agreeing to supply the materials from his own estates. Such were the influences that produced in this district skilful carpenters and joiners of the type of Richard Dale.

This man probably learnt his trade from his father or from some relative or neighbour, and served an apprenticeship extending over many years at the bench and on the scaffold. During this time he would learn how to convert timber from the fallen trunk, he would master the methods of construction then in vogue, and become familiar with the traditional kinds of mouldings and ornament in common use; adding to his work that touch of individual fancy according as Nature had gifted him. In all probability his knowledge of the world was restricted to a circuit of a few miles from his native place, and he would remain within the spell of the same influences in which he was born.

The neighbouring church of Astbury owes some portion at least of its fine timber roof to this ingenious carpenter, as his name is cut on one of the main timbers.

The woodcarving at Moreton, though instinct with life and vigorously executed, is somewhat rude and coarse—plebeian, one might call it. Certainly it falls far short of the attainments of the mediæval carver both in design and execution, and altogether lacks the refinement of Italian Renaissance work. Still it possesses an eminently wooden quality and considerable variety of motive, besides being in good scale—qualities altogether absent in the realistic productions of the more scholarly and polished Grinling Gibbons school.



LITTLE MORETON HALL: THE BALLROOM.

The mouldings, on the other hand, are on the whole beautifully proportioned, simple in contour and workmanlike, and the shafts and mullions possess an appearance of structural sufficiency and strength, without a suggestion of heaviness, that contributes in no slight degree to the happy result of the whole composition.

The barge-boards are entirely free from ornament, but the present ones have all the appearance of modern execution; and, judging by the richness of the rest of the work, it is highly probable that their predecessors were enriched with carved ornament. Presumably the painted decoration on the plaster coves and panels is merely legitimate restoration, but in any case the custom is to be deplored; for in buildings of this nature, in which detail is so abundant, plain spaces are to be jealously guarded as a valuable foil to the richer portions, and to afford rest to the eye, which is apt to become jaded and confused by the multiplicity of detail. Besides this, the applied ornaments compete unduly with the wooden braces between the main beams, which justify their existence by serving a useful purpose and at the same time relieve the squareness of the principal framework. The roofs are covered with large stone slabs, of soft brown colour, which harmonize admirably with the sombre tones of the timber.

Though externally Moreton presents practically the same appearance to-day as it did in the Elizabethan era, except for the mellowing influences of upwards of two hundred years, the interior has suffered many minor modifications owing to constant changes of fashion, which, however tolerant of the outside appearance, has been wont to allow but little latitude from the accepted standard inside the home. Most of the original fireplaces have been mutilated or modernized; alterations of plan have taken place; a partition was constructed across the principal apartment in the front wing on the first-floor; and the ties and struts introduced, not always with the highest taste but with the best intentions, however necessary, do not add to the effect. Many of the floors have been concreted to preserve them from destruction; the walls have settled in all directions, so that the framework is alarmingly out of the perpendicular, and the floors undulate to an extraordinary extent. But with all these defects the interior is very fine, very massive, very beautiful.

The staircases without exception are of the spiral kind, constructed round an oak post at least 12in. across.

Plasterwork, for which the Elizabethan period was so noted, is only to be found in the upper storey of the front range. At one end of the ballroom in the gable over the window is a figure of Fortune poised on a wheel modelled in this material, and surrounded by a highly conventionalized and somewhat thin ornament based on the vine and bearing the legend "The wheel of fortune whose rule is ignorance." The corresponding gable at the other end of the apartment is decorated with a female figure of Fate, bordered by a similar pattern and bearing the legend, "The speare of destinye whose ruler is knowledge."

Another example of plasterwork is the fireplace in the small room adjoining the ballroom. But this is scarcely satisfactory, as it undoubtedly suggests stone construction and technique. The coat-of-arms in the panel is that of the Moreton family quartered with Macclesfield, surmounted by the greyhound, the Moreton crest.

There are some large wooden Renaissance brackets in the state apartments below, carved with considerable spirit and elegance, but they look somewhat out of place, supporting the moulded Gothic wood beams of the ceiling. Similar objection may be taken to the panelled brackets under the feet of the roof principals in the ballroom, the brackets appearing altogether out of proportion to the slender timbers they appear to support.

The leaded glazing, which is wrought in a vast variety of patterns, is said to be a faithful restoration of the older lights.

Little Moreton-cum-Rode is mentioned as two manors in Domesday book. Moreton was granted with other estates to William Fitz Nigel, in recognition of his services to the Conqueror. The new owner let the estate in fee to a knight, who after the prevailing custom adopted the name of Moreton for his patronymic. This family continued to inherit in the direct male line until the reign of Henry VIII., when Letitia Moreton conveyed the estate to Sir Graham de Lostock of Lostock Graham. Their grandson adopted the old family name, and his descendants continued to hold the manor until 1763, when the Reverend Richard Taylor, nephew of Sir William Moreton, Recorder of London, who was the last of the line, took possession and assumed the Moreton name. The property now belongs to the only surviving grand-daughter of the latter, a lady who took the veil and retired to Clewer, near Windsor, years ago.

In the year 1521 a dispute arose between Mr. Thomas Rode, proprietor of a neighbouring estate, and William Moreton as to who should take precedence in church and in processions, and William Brereton, of Brereton Hall, was called upon to settle this delicate question. The arbitrator with commendable judgment decided "that whyther of the said gentlymen may dispende in landes by title of inheritance 10 marks or more than the other, that he shall have the pre-eminence in sitting in the churche, and in gooing in procession, with all other lyke causes in that behalf."

This rivalry, though not always concerned with the same parties, appears to have been a standing grievance, as in the reign of Queen Elizabeth we find that an order was made, "that in the highest pew north side where the Mayor was accustomed to sit, that Richard Spencer Alderman should sit and be placed, in that his ancestors were builders of the same chancel." And in the same order William Moreton was assigned the first seat on the south side.

A certain Mr. Brook, a Presbyterian divine who earned the nickname of "Brawling Brook," and had the misfortune to be dispossessed of the living of Astbury at the Restoration, was befriended by William Moreton and was allowed the use of the private chapel until his death in 1664, at the age of seventy-two.

There are other reliques of the ancient inhabitants and visitors of this old house. On a window pane of one of the bedrooms are still legible the names of John and Mary Woodnothe, and beneath the following couplet :—

Man can noe more know woemen's mind by teares
Then by her shadow hede ye what clothes she weares.

John Woodnothe, who inherited Shavington Hall in 1634, married Mary, eldest daughter of William Moreton, the grandson of that William Moreton who erected the additions to the Hall in 1559. Apparently the lady was subject to moods, and puzzled her husband not a little.

Many other names are discernible—members and connections of the family—but the neatest couplet remaining is that scratched by an unknown hand upon one of the windows of the ballroom. It reads as follows :—

I stay here both day and night
To keep out cold and let in light.

Some of the Mortons cut no mean figure in their day. This Richard Moreton distinguished himself by marrying the heir to the Macclesfield estates in the reign of Edward III., which property he duly added to his own. Ralph, who died about 1509, probably erected the oldest portions of the present buildings. William, grandson to the latter, whom we have had frequent occasion to mention, died in 1563, a few years after the completion of his building operations. Dr. Edward Moreton was an eminent divine who married a niece of Archbishop Laud. Sir William, the last of the second line of Moretons, was Recorder of London.

Still, as we said before, thy ancient walls tell their own story, Old Moreton! And as we turn from the musty annals of a by-gone age, to take one longing lingering look of farewell, we cannot forbear to express our thankfulness to see thee in the hands of one who loves and cherishes thy crumbling fabric; with tender care adding the prop and buttress wherever demanded by the accumulating infirmities of age, without defacing or injuring thy quaint and picturesque beauty.

ARCHITECTURAL ASSOCIATION.

ENGLISH DOMESTIC ARCHITECTURE, 1100-1800.

BY J. ALFRED GOTCH, F.R.I.B.A.

A MEETING of the Architectural Association was held on Friday evening last, the chair being occupied by the president, Mr. Seth-Smith. After the minutes of the previous meeting had been read and confirmed, Mr. A. D. Thacker (London, W.) and Mr. G. M. Page (London, S.W.) were elected members of the Association.

The president announced the following additional donations to the New Premises Fund :—

	£	s.	d.
T. G. Jackson, R.A. - - - -	50	0	0
F. T. Baggallay - - - - -	31	10	0
A. Saxon Snell - - - - -	26	5	0
John Slater - - - - -	26	5	0
E. J. May - - - - - -	21	0	0
S. Flint Clarkson - - - - -	10	10	0
Hippolyte J. Blanc - - - -	10	0	0
G. C. Ashlin - - - - -	5	5	0
H. B. Creswell - - - - -	5	5	0
C. Harston - - - - -	5	5	0
T. H. Russell - - - - -	5	5	0
E. Howley Sim - - - - -	5	5	0
B. H. Webb - - - - -	5	5	0
W. Woodward - - - - -	5	5	0
G. B. Carvill - - - - -	5	5	0
E. R. Chambers - - - - -	5	0	0
A. Hill - - - - - -	5	0	0
H. S. Noblett - - - - -	5	0	0
A. H. Belcher - - - - -	3	3	0
W. Stewart - - - - -	3	3	0
H. Cayley - - - - - -	2	10	0
H. Lovegrove - - - - -	2	2	0
W. L. Lucas - - - - -	2	0	0
Cole A. Adams - - - - -	1	1	0
E. A. Agutter - - - - -	1	1	0
C. M. Armstrong - - - -	1	1	0
W. J. Devlin - - - - -	1	1	0
S. J. Tatchell - - - - -	1	1	0
A. S. Tayler - - - - -	1	1	0
J. T. Woodard - - - - -	1	1	0
	252	15	0
Donations previously announced	3,183	17	0
Total - - -	£3,436	12	0

He remarked that they would be very pleased to receive small donations from their members; it was just those which expressed the sympathy with the scheme which they desired, and he therefore urged members not to be deterred for fear of comparison with the larger donations of other men. He also stated that the Fund was kept entirely separate from the rest of the Association's affairs. The president then announced that the spring term of the Day School would commence on January 13th, and in doing so he said that nothing could be more satisfactory than the work done during the first three months of the school.

Mr. J. Alfred Gotch then read a paper on "The Development of Domestic Architecture in England from the Twelfth to the Eighteenth Century." He said :—

The subject is large; so large that one-half of it has filled the four portly volumes of Messrs. Turner & Parker on the "Domestic Architecture of the Middle Ages," and as that work would take, on a moderate computation, four-and-twenty hours to read aloud to you, without any interval for rest or refreshment, it is quite obvious that the view of the subject which we take this evening must be cursory and confined to but a small part of the whole range of research.

The Rooms.

In the present day we should classify the accommodation of a house in three main divisions: the reception-rooms, the bedrooms, and the kitchens or servants' quarters. Going back to the times of the early Georges, the same classification holds good, but the bedrooms were less important, and the reception-rooms much more so. Still further back, in Elizabeth's days the same division is applicable, but we find the chief apartment among the reception-rooms to be the great hall. The bedrooms were largely left to take care of themselves. In all three periods the kitchen department is fairly commodious. But if we go back to the thirteenth or, further, to the twelfth century, the bedrooms practically disappear, and only the reception-rooms and the kitchens remain. Indeed, when we reach these primitive times it becomes necessary to alter our classification somewhat. There are still three kinds of rooms, but they consist of hall, solar, and kitchens, the solar being the private apartment of the master, or, to use a more appropriate word, the lord. These three rooms are the nucleus from which grew the vast mansions of Elizabeth and Anne; and the development of domestic architecture consists largely of the development of this one single apartment for the lord into the separate apartments which are now provided for each of his household.

Houses in the Middle Ages.

There is this initial difficulty in investigating the houses of the early Middle Ages—that most of them have disappeared. They were as a rule built of wood and plaster, only some of the more important being of durable materials. Those which have survived have suffered so many alterations in the course of their existence that their original arrangements are not always to be made out. Nevertheless, from such remains as survive and from the rare references to such matters as have come down to us in contemporary writings, it is quite clear that houses consisted of, first and foremost, a hall, then at one end the solar or solerre (as it is also called), and at the other the kitchen with its subsidiary apartments.

The houses of that time were comparatively limited in number. There were the king's houses (of which he had a good many in different parts of the country), the houses of the great barons, and the manor-houses. Besides these there were the great religious establishments, which, however, had their own special arrangements, hardly falling within the scope of this paper.

Many of the great barons lived in highly fortified houses, which we call castles, some of which were actually military strongholds. In the case of others it is not easy to draw a distinct line between the castle and the house, for they were all more or less fortified. But at present it is not the military strongholds which are under consideration, but those dwellings which were only fortified in order to secure their inhabitants. Such a house was the Peak Castle, in Derbyshire. The dwelling part was the keep or tower, the ruins of which still crown the summit of the isolated piece of land. This keep resembles the peel towers of the Scottish border, many of which still remain both in Northumberland and in the Lowlands of Scotland. It is a square tower of three or four storeys, each floor containing one room. The basement was a cellar; the floor above it contained the hall; over the hall was the lord's private apartment. This arrangement is very primitive, and represents what must have been the minimum in the way of accommodation which was tolerated. This vertical disposition of rooms, one over the other, soon gave way to a disposition which placed most of them on the ground floor, or if they were not on the ground floor they were spread out into a form less rigidly vertical.

Whatever arrangement was adopted, however, the hall was the chief apartment. It was the largest, the most permanent, and the most central. It was, in fact, the dwelling-place of the household, and became synonymous with the house itself, which was in most parishes known as "The Hall." In this apartment the whole household lived, ate and slept; all save the lord and, possibly, his family, who had a separate room into which they could retire, already mentioned as the solar. The solar appears to have been almost always an upper chamber, built over an apartment which was often used as a store place; but there are so few remains of these very early houses that the exact arrangements can hardly be made out with certainty. The solar seems to have been approached in many cases by an outside staircase. But, at any rate, this much is clear, that the hall stood in the middle, between the solar and the kitchen, the latter being the third of the three main classes of rooms which these early houses contained. The cooking was not done in the hall, but in a separate building devoted to the purpose, attached to which were a few subsidiary rooms such as the larder, where the food was kept; the sewery, where provisions, linen and table furniture were stored; the cellar, which was used for general stores and wine; and the buttery, where the drink was distributed. These smaller rooms were not always provided—their presence depended on the importance and size of the house; but there were always and in every house the three divisions of hall, solar and kitchen, the hall lying between the other two. The arrangement of the hall was simple, and remained the same in principle from the earliest times down to the seventeenth century. It then underwent a change which marked a complete revolution in domestic architecture, and which will be described in due course.

The hall, lying, as already said, between the solar at the upper end and the kitchen at the lower, was entered, close to the latter, by a door in its side wall. Through the lower end wall were doors leading to the kitchen department—sometimes two, sometimes three. Of these one opened into the buttery, one into the kitchen or kitchen passage, and the third (if there were a third) into the pantry. There was usually a screen stretching across the hall to keep off the draught from the open door, and more particularly to screen off the kitchen traffic, for draughts would still come through the windows, which were seldom glazed in early times. There were doors (generally two) through the screen into the hall itself, and there was a ceiling to the passage cut off by the screen, which formed a gallery usually known as the minstrels' gallery, although it is tolerably certain that very few of the ordinary households could have supported a private band. At the end of the hall, away from the screen, was the daïs, which was a raised platform, a few inches high, whereon the lord and his family and principal guests sat to dine. In this upper end of the hall was a doorway leading more or less directly into the solar.

Oakham Castle.

Both the solar and the kitchens were sometimes built of wood, as were also many of the subsidiary apartments. Such fragile buildings have disappeared, leaving in some cases little besides the hall to tell of the former extent of the house. This may have been the case at Oakham Castle, where the hall alone remains of the building erected about the year 1180 by Walkelin de Ferrers. But this hall is an extremely fine example of its kind; it is of considerable width, and the roof is carried in three spans, one over a central nave and the other two in the shape of a lean-to against it—an arrangement similar to that adopted in churches, and serving to remind us of the similarity of treatment adopted in both ecclesiastical and domestic buildings.

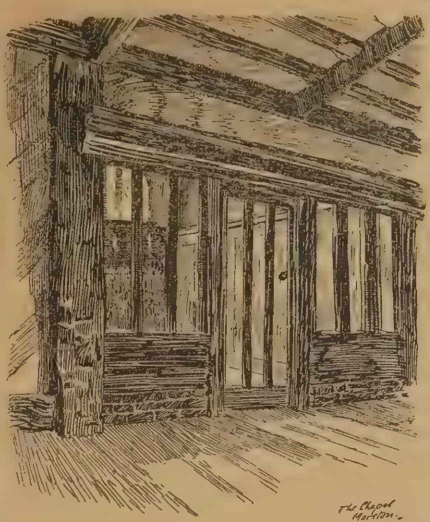
The windows are small and low down, and they have in common with the doorway the characteristics that distinguish the transition from Norman to Early English. The interior might well be taken for that of a church, with nave and aisles; but the position of the doorways in the end walls, the treatment of the windows on the inside, as well as the absence of any indication of a chancel, would put the wary enquirer on his guard. The hall stands alone, the solar and kitchens—which must have existed—having disappeared. It may be that they were burnt, for accidents of that kind happened not infrequently. If not burnt down, these rooms may have been blown down, as were the royal kitchens at Oxford in the seventeenth year of Henry III.

It seems quite clear from these and other specific references that many of the subsidiary rooms were built of wood, although the hall was of more durable materials.

Personal comfort was not much studied in those days; men were content to sleep where they could; and as they were not particular about their beds, so also they had simpler views than we have about the heating of their rooms. In some houses only the solar had a fireplace; the hall was heated by a fire in its midst, the smoke finding its way out of a louvre on the roof. Here and there the hall had a fireplace of its own. The smoke from the central fire found other vents than the louvre, for but few of the windows were glazed; wooden shutters served to keep out the weather. In some grand houses the part above the transom was glazed, while that below retained its shutters. But people were susceptible to draughts even in those hardy days, for Henry III. directed a window in the queen's room in the Tower to be glazed, "so that the chamber might not be so windy." It was in his reign, too, that the practice of wainscotting rooms—that is, lining the walls or the roof with wood—was introduced.

Stokesay.

At Stokesay, which was built in the thirteenth century, the main dispositions conform to the usual type. There is the large hall entered at the end of one of its sides. At its upper end is a door which eventually gave access to an outside staircase leading to the solar. At its lower end is a cellar, over which is an apartment with a fireplace. This room was reached by a staircase in the hall, standing in what would ordinarily be the screens. Of the kitchen there do not appear to be any remains. Beyond the upper end of the hall is a tower which was used for defensive purposes, upon the particulars of which it is not now needful to dwell. The details of the work are characteristic of the thirteenth century. The hall windows are of two pointed lights surmounted by a circle. The lights, which are divided horizontally by a transom, were provided with shutters, but the circle was apparently always open for the winds of heaven to blow through, and doubtless it was through them that most of the smoke from the central hearth escaped.



LITTLE MORETON HALL : THE CHAPEL.

Yanwath Hall.

Yanwath or Yanwith Hall, in Westmorland, was built early in the fourteenth century, but underwent considerable alterations in the sixteenth. The same arrangement was adopted here as in the former examples. The great hall was approached through a passage, which was enclosed by a stone wall on both sides instead of having one side formed by the wood screen of the hall. On the left of the passage was the kitchen, on the right was the hall. The hall itself had a fireplace instead of a central hearth, and this fireplace was at the lower end of the hall. In later times it was more usually placed near the lord's end. There is also a bay window—a feature which became subsequently of universal adoption. The solar in this instance is developed into several rooms, situated in a tower, and exhibiting the usual characteristics of the accommodation of a peel-tower—namely, one fair-sized room on each floor surrounded by thick walls, in which are contrived various diminutive apartments, access being obtained from floor to floor by means of a narrow newel staircase.

In addition to the usual accommodation which has hitherto been mentioned, Yanwath had a number of other rooms arranged so as to form an enclosed courtyard, one side of which has, however, disappeared. The entrance to this courtyard was through a gateway nearly opposite to the hall door. This courtyard idea, which arose from the necessity for defence, lingered on, as we shall see, for reasons of appearance, long after the need for defence had ceased.

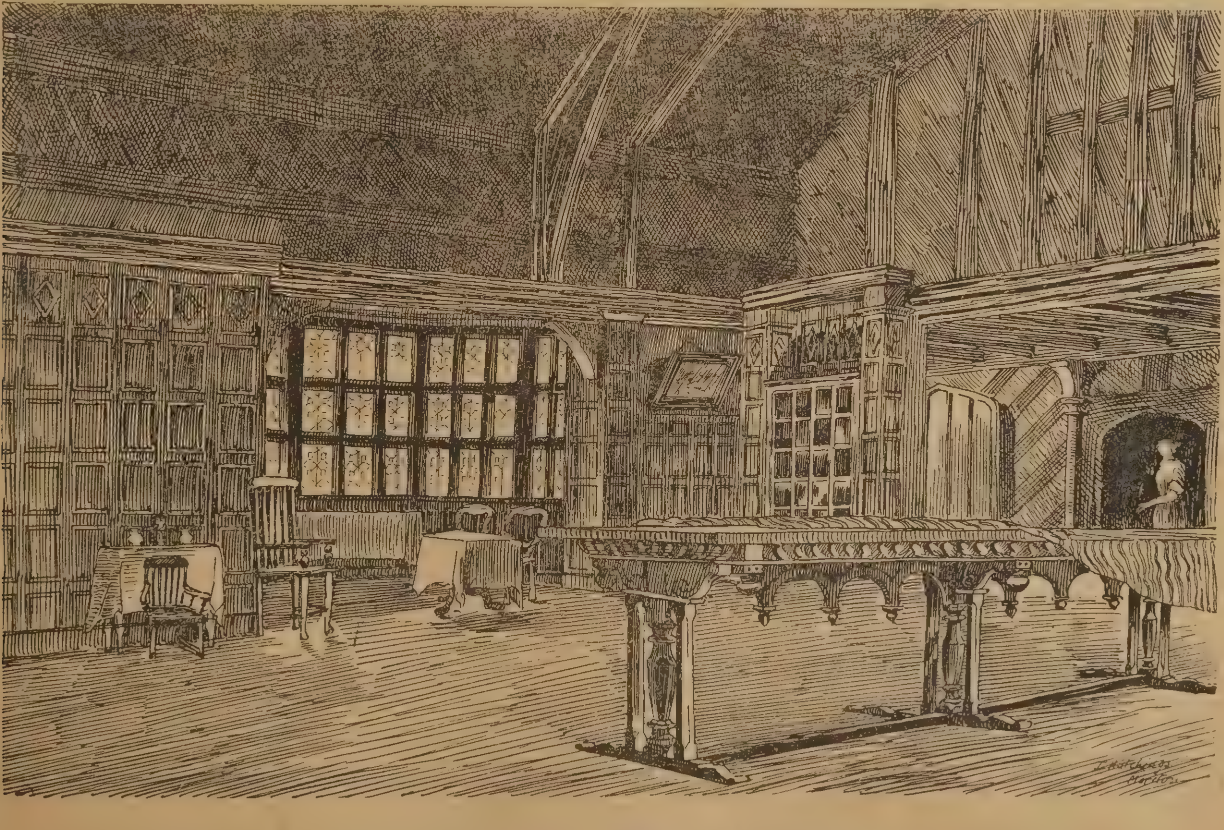
At Sutton Courtney,

in Berkshire, is a house built about the middle of the fourteenth century in which the usual disposition of rooms is again found. There is no bay window to the hall, but it is worthy of note that below the main window at the daïs end is a low side window, probably contrived for the pleasure of the occupants of the daïs. In later times, while the hall windows were almost invariably high up from the floor, the bay window of the daïs was equally invariably brought down low enough to afford an outlook. The lofty hall roof still remains (or remained when Turner and Parker wrote), and the general character of the work led to the hall being called the chapel—another illustration of the wide-spread but fallacious notion that Gothic forms of necessity indicate a religious edifice.

The hall itself was usually a lofty building, with an open-timbered roof. It divided the house into two separate halves, which, if they were of two storeys, had to have their own separate staircases. The walls of the hall were often plastered, and for ornament they were hung with the spoils of the chase, or else with pikes, guns and bows, with old swords and bucklers that had borne many shrewd blows. A good example is to be seen at Cothele, in Cornwall, and also at Haddon Hall, where the fifteenth-century wood screen still remains.

Haddon

is a fine example of a large fifteenth-century house built round two courts, and still exhibiting a considerable desire for defence. The hall, as was usual in double-courted houses, was placed in a wing between the two courts, thus being in the most central and best protected position. It was flanked, according to the usual custom, at one end by the buttery, pantry and kitchen, and at the other by the family apartments, hitherto confined to the solar, but now developing into the parlour and other rooms, including a number of separate bedrooms. The plan of Haddon shows the great chamber,



LITTLE MORETON HALL : THE BANQUETING HALL.

and the long gallery, but it should be remembered that the great chamber was probably not so called prior to the sixteenth-century, while the long gallery was contrived over the walls of a number of earlier rooms towards the close of that century. The kitchens here are much more elaborate than in any of the previous examples, and they go to show that the wants of a large household and a hospitable lord were both great and permanent, and not so liable as in ancient days to interruption from hostile visitors.

The possibility of such interruptions was never absent from the minds of the builders of those days. Houses were nearly always surrounded by a moat where the nature of the ground permitted it. The entrance gateways still followed in many cases the ancient fashion of placing an archway between two towers. The courtyard plan still held the field in houses of any pretensions. As the years went on the character of the ornament changed, just as it changed in churches. The tracery disappeared from the windows, which became flat-headed; doorways likewise became less aspiring, and assumed the obtuse angle of the Tudors. Fan tracery made its appearance in various places, such as the ceilings of bay windows and porches; circular stairs were placed in turrets, which were carried up above the main block of the building and crowned with lead cupolas. The splendid brick chimneys of Henry VII. made their appearance, with all their intricacy of cut and moulded brickwork.

Then came

The Italian Influence,

which first made itself felt in unimportant ornament, and then spread to shaping the building itself, reducing it to symmetry so far as the exterior was concerned, but leaving the interior still to be arranged after the old fashion.

It brought also that exotic feature, the loggia, or open arcade, which, however, never obtained a really firm footing in English houses. Indeed, all through the sixteenth-century and the first quarter of the seventeenth the new Italian influence never overmastered the old irregular English habits. But under the accomplished Inigo Jones, as we shall presently see, symmetry, which had hitherto been kept to the outside of the house, invaded the inside as well.

Elizabethan Plans.

However much the character of the ornament may have varied, the character of the plan moved but slowly and always in one direction. Haddon and Apethorpe, two large houses, have shown how the old type grew at its two ends, the hall remaining as of old, but the kitchen and the private apartments undergoing considerable increase and development. On a smaller scale Canons Ashby tells the same story. So do the plans of Elizabeth's time, such as Cannons on a small scale and Kirby on a large scale, both taken from Thorpe's book. In looking at these plans it is obvious that the old idea is still the foundation of the arrangements, although in a great place like Kirby the accessory apartments have become vastly multiplied, and all thought of defence has been abandoned. Houses are no longer built for safety, but for show. Windows which once were sparingly introduced into the outside walls—that is, the walls looking out on to the country—are now used without restraint, and are regarded quite as much from the point of view of how they will help the composition of the design as from that of usefulness in lighting the rooms. Cheerfulness, splendour, comfort (of a kind)—these are the qualities now sought after. The hall had long ceased to be used as a sleeping apartment.

It was not always used even as an eating place. Not only had the ancient solar developed into the parlour, but the parlour had been developed into the summer parlour, the winter parlour, and the dining parlour. It was no longer on the upper floors, but close to the hall on the ground floor. It was no longer the only bedroom, for bedrooms had been indefinitely multiplied, and, under the name of "lodging," fill up any space in old plans to which no more fitting name could be given. The solar had still further developed. In addition to the parlours on the ground floor, there had arisen the great chamber on the upper floor, and the long gallery—that feature peculiar to Elizabethan houses.

Internal Finishing and Decorating.

The finishing and embellishment of these rooms had developed along with their number. In the days of Henry III. we hear of plastered walls, and wainscotted walls and roof, but the rooms were extremely draughty, and the smoke from the central fires must have been almost intolerable; there was, indeed, no great inducement to abolish draughts so long as the smoke hung about the room. But the discomfort of draughts and smoke gradually told, even on the iron constitutions of mediæval knights, and by degrees fireplaces with a special flue for the smoke grew more common, and the smaller rooms were furnished with them. Draughts were excluded by filling the windows with glass, and later by plastering the ceilings as well as the walls. Indeed, the ceilings were plastered more frequently than the walls, which were usually covered either with tapestry or with panelling. The plaster on the ceilings was not kept plain, as it usually is in our days, but was worked into an infinite variety of ornamental patterns. Indeed, by the period at which our story has now arrived, the fitting up of rooms had reached a point of development beyond which we have not gone very far.

Down to the end of the sixteenth century, and, indeed, as far as the first quarter of the seventeenth, the old type of house plan was still used—the old type which had prevailed in the days of the Norman kings. It is true that the ancient idea had been greatly developed; the kitchen department had been so much enlarged as sometimes to require a court to itself. The single private room, the solar, had been multiplied into several parlours, the great chamber, the long gallery, and many "lodgings" or bedrooms. But the hall still remained the centre of household life, and the daïs, which indicates its use as a living room, is shown on nearly all the plans in Thorpe's book. This enormous development of household convenience and comfort would, of course, have been impossible had the first idea of the builders been, as of old, to secure safety; but it was not, and as the certainty increased that a man need not depend upon his own efforts to preserve his security, but the public authorities, so he found more leisure to attend to his comfort, and for securing greater privacy for himself and the members of his household. The great hall began to feel the influence of this change; it had long ceased to be used as a sleeping apartment, and now it ceased to be used for meals. The family withdrew at one end, the servants at the other, and it became merely a vestibule. Concurrently with this change of use there went a change of idea in planning. The symmetrical disposition of houses which the Italian influence produced demanded that the hall should be central. Long-established custom demanded an entrance at one end of the hall, in the "screens," which, therefore, could not be in the centre of the façade. There are a number of examples, both in Thorpe's plans and in actual houses, of how these difficulties were surmounted. But when the hall was no longer wanted as a living room, there was no longer need for the entrance to be in its old position at the end, and the imperious demands of symmetry were satisfied by placing the hall in the centre of the façade and the entrance door in the centre of the hall. This point is curiously illustrated by comparing Thorpe's plan of Aston Hall with that of the house as built. Thorpe shows the door in the old-fashioned situation at the end; it was actually built in the centre, and the hall here definitely ceased to be a living-room and became a vestibule. This change is a momentous one, for it brings us out of the mediæval idea into the modern.

But although at Aston the plan shows a new departure so far as the hall is concerned, it still follows the old lines in its general grouping, and so does the external appearance. The triumph of foreign fashions over native was, however, near at hand, and it was Inigo Jones who brought it about. At

Raynham Hall and Coleshill

the plan is no longer founded on the old type. The hall is not the chief apartment, with the family at one end and the servants at the other. The latter have descended into a basement, and the whole ground floor is occupied by family rooms. Traces of the old fashions remain in the projecting wings and in the gables with which they are roofed. But in Coleshill, another house of Inigo Jones, the foreign influence is even more marked, the plan is still more symmetrical, the elevations are still more classic. In neither house are the windows mullioned; they have sashes, and the change from mullions to sashes marks the final disappearance of the last traces of mediæval treatment.

The lesson in foreign fashions which Jones gave his countrymen were continued by Wren, and bettered by his successors in the eighteenth century. At Raynham and Coleshill one cannot help thinking that the snugness of home is sacrificed to the demands of stateliness; but at Blackheath and Keddlestone it is lost altogether, and the inhabitants of those great houses must daily pay a penalty inflicted by grandeur. The component parts of the house are divided into separate blocks with tiresome corridors of communication.

The great houses of the eighteenth century make a brave show, but they exhibit a profound scorn for the small amenities of household life. They were build in an artificial age, and, like the huge wigs which their builders wore as an indispensable part of their costume, they were intended rather for the admiration of the beholder than the comfort of the owner.

But the pursuit of comfort, which was the propelling force in all the changes of domestic architecture which we have been tracing, although it was neglected by the great in the days of Anne and the Georges, was still followed by persons of humbler ambitions, and in the smaller houses of the eighteenth century there is much that is admirable. Much skill and care was expended upon their internal embellishment, and the woodwork of that period is always worth our careful study. This is not the occasion upon which to enter on a minute description of the respects in which it differed from that of Elizabeth's time; this only need be said, that it followed the general tendency of domestic architecture in adopting largeness of scale and dropping minuteness of parts. Wilton House and the Brewers' Hall sufficiently indicate the change of treatment.

This long story must now come to an end. It has not dwelt much on details; it has rather sought to show that our domestic architecture has undergone a real process of evolution, and that it has reflected, as indeed one might suppose that it would, the habits and wants of well to-do English people. A continuous thread runs through the whole series from the Conqueror to the Georges, and the vast Palace of Blenheim can trace its origin back to the lonely little tower perched on the hill above the Peak Cavern at Castleton.

The president observed how happily Mr. Gotch's book on "Early Renaissance Architecture in England" fitted in with Mr. Blomfield's work dealing with the succeeding development. With regard to the paper they had just heard he remarked that wherever necessity dictated any particular form or planning, that necessity was ever conservative, and, consequently, we saw how very gradual was the adoption of any new feature; but this would not hold good in regard to ornament, which seemed more to be ruled by fashion. Mr. Douglass Mathews moved a vote of thanks to the lecturer, which was seconded by Mr. H. H. Statham. Mr. Arnold Mitchell, Mr. G. M. Nicholson and Mr. N. F. Barwell also spoke, Mr. Mitchell giving some personal recollections of a stay in a large Elizabethan house to illustrate how awkward the planning was from the standpoint of household service and convenience. Mr. Gotch replied, and the meeting then ended.

A New Police Station at Arundel is being erected. It is a red brick and stone building situated practically next door to the present police station; and in addition to the living accommodation for the superintendent there is a charge room and office, with four cells at the rear of the premises. Hitherto it has not been possible to keep a prisoner at Arundel who was under remand, because the present cells at the town hall are underground. The provision of the new cells will, therefore, be not only a convenience but a saving of the expense incurred in sending prisoners to Portsmouth while under remand.

Bricks and Mortar.

APHORISM FOR THE WEEK.

Beauty in the arts is but a natural or educational prejudice, and inconstant, since it depends only upon the fashion of the time.—M. FREZIER.

Our Plates. THE proposed country house by Mr. W. Kidd is to be built at Pinner. On the ground floor are arranged entrance hall, drawing-room, dining-hall and schoolroom, kitchen and offices, &c.; and on the first floor four bedrooms, boxroom, bathroom, &c. The floor of the entrance hall will be laid with black and red tiles, showing broad cement jointing, the walls to be plastered and coloured in terra-cotta, with 15in. dead white frieze, around which would be written in old English characters, "If ye come as a friend, enter, and peace be with thee; if as an enemy, enter not in the guise of friendship." The staircase to be in oak, with square newels and balusters taken up to ceiling. The dining-hall would be plastered and distempered pale grey-green to a height of 7ft. 6in. with a broad flat frieze rail, and the frieze to be of plaster tinted a warm cream. The floor joists of the room above show in the dining-hall proper, and would be of heavier section than usually required, but spaced 2ft. apart, the ceiling being taken half-way up these joists and attached to a frieze simply by a cove. From the frieze rail would hang an arras of casement flax material a shade deeper than the walls, hung flat, at the top of which a design representing a hunting scene in colours of white, brown, orange and purple would be appliqued. At the end of the dining-hall is arranged an ingle-nook of sufficient size to allow one to sit comfortably in it, the floor of which would be in tiles of various shades, showing broad cement joints; and the ceiling is kept 15in. below that of dining-hall. The drawing-room would be decorated in shades of rose, blue, purple and orange, with a frieze representing an old-fashioned garden and all woodwork painted ivory-white. The schoolroom has been designed in a manner which will take away the usual severity of this class of room, and is panelled to a height of 4ft. 6in., above which would be stencilled a design representing several nursery rhymes. The principal bedrooms will be decorated in similar schemes. The internal decorations have been designed by the architect, and the friezes in the drawing-room and schoolroom will be executed by him. The elevations are treated in cream rough-cast, with blue-brick string-courses at the floor levels; all casement windowsto be leaded-lights; the roof to be of dark-green slates. Care has also been taken in the arrangement of the garden to give as small contrast in colour as possible.—The White House, Ealing, is to be in brick and rough-cast, with dark-blue brick string-courses, the window frames to be flush with the face of the wall, and the roof to be of dark-green slates.—The original rood-screen at Cranfield Church, judging from the fragments remaining, was one of the greatest interest and beauty, and this design (which was accepted for last year's Royal Academy) has been made from a very careful and minute study of the few pieces left. The date of it was clearly of the end of the fifteenth or the beginning of the sixteenth century. It shows in parts most interesting evidence of the influence of the Italian Renaissance, not so much in the mouldings and tracery as in the smaller details of the carving in the panels; this is more evident in the two end panels, which are solid, and were evidently the last portions of the screen to be completed. In making the drawings for the screen the architect's aim has been to retain the whole of the old work, but to give to the design a distinct twentieth-century feeling, so as to speak clearly of its reconstruction in this century.—The house at Munstead, near Godalming, was designed for Mr. William R. Pullman. It is situated in the midst of a pine wood. The roof is covered with green Tilberthwaite slates, and the whole of the walls with Portland-cement rough-cast. Internally the dining-room is panelled with oak, and the hall with cedar-wood of extremely beautiful grain. Miss Gertrude Jekyll has designed the gardens. The builders were Messrs. Kingerlee & Sons, of Oxford.

Egyptian Rock Tombs. THE ROCK TOMBS OF SHEIKH-SAID are described by Mr. N. de G. Davies in the Tenth Memoir just issued by the Archæological Survey of Egypt. This necropolis, excavated in the cliffs on the eastern bank of the Nile, about 180 miles south of Cairo, apparently formed one of the chief places of burial for persons of importance in the district. The tombs, which have already engaged the attention of explorers, are rock-cut chambers, sometimes single, sometimes connected, scattered irregularly along the line of crags, and are unfortunately often much dilapidated. As they formed a local centre, not directly connected with the general history of the kingdom, their dates are not easily determined, but one of the most important can be linked with the fifth dynasty, and some in an inferior style may be as late as the seventh or eighth dynasties. Graffiti and other remains show that certain of them were used as Coptic dwellings, probably about the fourth century of the present era—one, indeed, much to its detriment, having been converted into a church. But the decorations are often interesting, particularly those in the rich tomb of Urarna, together with that of his father. They were princes, apparently in the fifth dynasty, who ruled the hare nome or province, and these sepulchres give a vivid picture of the life and occupations of the ancient Egyptians more than 5,000 years ago.

Lord Leighton's House. THE royal borough of Kensington has distinguished itself by resolving to accept the gift of the sisters of the late Lord Leighton and to assume the care and management of Lord Leighton's house. For some time past the house has been open to the public, and all who have seen it will have realized the importance of permanently securing the house and its contents to the public. The distinguishing features of the house are its suite of studios and the celebrated Arab Hall. In this hall Lord Leighton gave rein to his passion for rich colour and beauty of workmanship. The walls are lined with exquisite Persian tiles of the best period, the light is admitted through full-tinted Damascene glass and Caneni lattice-work. The studios are equally characteristic. They are workshops, but not mere workshops. The large studio is a carefully-designed room of considerable size, used by its former owner as a music-room as well as a studio. Since the house has been open to the public this studio has been the scene of many lectures and concerts. It will seat about 150 to 200 persons, and is an ideal room for chamber music. The glass studio is equally well suited for such exhibitions of paintings or engravings. Sketches illustrative of folklore and fairy tales, Constable engravings, and examples of stipple work have successively been shown to great advantage in this room. There is still another studio, known as the Silk-room, from a corner of which a glimpse of the Arab Hall may be had. This again is well adapted to be the permanent home of fine studies and drawings. Lord Leighton's methods are well known. Every finished picture was preceded by a long series of studies. Every figure, almost every limb of every figure, was separately sketched, and not once, but often, and under varying conditions. Drapery was arranged and rearranged, groups were compared, coloured sketches made. Fortunately these chips of the workshop have been preserved, and with them the house is now furnished. Under the management of the council the house will, of course, be open every day free of charge. While Lord Leighton's own sketches will always constitute a principal feature of the house, there will be place in the ordinary living rooms for any art collections of the borough, while the glass studio will be available, as hitherto, for special loan exhibitions from time to time.

Woodcarving by Machinery. IN view of the fact that two-thirds of the furniture now made in Great Britain is made by machinery, it is interesting to note some remarks which recently appeared in the "Times" on this subject. The writer said: "Not only do the machines produce sections or parts of furniture by the hundred or the thousand in a marvellously short space of time; there is the further consideration that the machines do work of a kind that seems almost incredible. There is, for instance, an automatic carving machine which is a perfect marvel of ingenuity. A workman puts a piece of timber into the machine, which he locks up, sets going, and then leaves to itself. Half an hour later he returns, finds that the machine has stopped of its own accord, reopens it, and takes out the piece of timber, converted into an elaborately carved panel. This, when it has been finished off, could not be distinguished from a similar panel which an ordinary woodcarver might take a week to produce by hand. There is another machine which, worked by a boy, will carve four panels at a time, the cutting tools being guided by a metal pattern, and each acting simultaneously on a piece of timber placed on a separate shelf in the machine. Thanks to such devices as these, cheap bedroom suites, for instance, can now be provided with an amount of ornamentation which would otherwise be impossible at the price." We would remark however, that "at the price" it would be better if there were not such an abundance of "ornamentation."

Enquiries Answered.

The services of a large staff of experts are at the disposal of readers who require information on architectural, constructional or legal matters. Questions should in all cases be addressed to the Editor. The querist's name and address must always be given, not necessarily for publication.

An Old Architectural Book.

BECCLES.—With regard to the enquiry on p. 350 of our last issue, a correspondent informs us that he possesses a copy of "Reigles des Cinq Ordres d'Architecture de Vignolle." It is dated 1657. The book is 6in. long by 4in. wide and about ½in. thick. It contains 102 pages, with a plate and description to each page.

Tar-Macadam Roads.

NORTHAMPTON. — ST. CRISPIN writes: "Kindly give some particulars about the construction of a tar-macadam road. Is it superior to ordinary macadam? What are the prices of each?"

The construction of tar-macadam roadways is fully described on p. 613 of "Specification No. 4." As mentioned, their only advantage over ordinary macadam roadways is that, being non-absorbent, they can be easily cleansed, they are more free from dust and mud, and effect an economy in watering and scavenging. The cost of tar-macadam roadways varies from 2s. to 2s. 6d. per yd. super., exclusive of the foundation. Ordinary macadam costs, on an average, about 11d. per yd. super.

Value of an Invention.

BLACKBURN.—CARBON writes: "What would an invention be worth that could be fitted up for about 10s. per room and would cause a fire to give 50 per cent. more heat and always burn better, absolutely prevent draughts, and give greater freedom from dust?"

Inventions relating to firegrates are multitudinous, and the majority of them never get beyond the Patent Office. Some persons seem to think that when they have secured a patent their difficulties are over; but they are only just then beginning, for it is in getting manufacturers or others to adopt inventions commercially that the difficulties occur. From the indefinite statement given us by "Carbon," it is impossible to estimate the value of his invention; it may be of value, or it may be an idea which has been patented already—perhaps many times, in modified forms. Even assuming it is a good invention, one cannot estimate what it would be worth; for that depends so largely on the firm to whom it is offered and the business capability of the inventor. It is worth just what he can get for it. If "Carbon" wants to ascertain the value of his invention, he had better patent it and then approach those likely to adopt it; he will soon find out then.

Horace Walpole's Villa at Strawberry Hill.

Southport.—F. H. C. writes: "Is Horace Walpole's villa at Strawberry Hill still in existence?"

There is a house at Strawberry Hill, near Twickenham, still standing which is known either as Pope's or as Walpole's villa. It is occupied by Mr. Labouchere. G. A. T. M.

The Term "Gothic."

Southport.—F. H. C. writes: "Evelyn, in his diary, under date 3rd January, 1666, uses the word 'Gothic' as applied to Nonesuch House. We are usually told that the word arose in the eighteenth century, and was applied to mediæval buildings as a term of reproach. In what sense does Evelyn use the word?"

I believe that the term "Gothic" was first used in the disputes in Parliament as to the design to be adopted for New St. Paul's, just about the date named by our correspondent (1666) and as a term of reproach.

R. I. B. A.

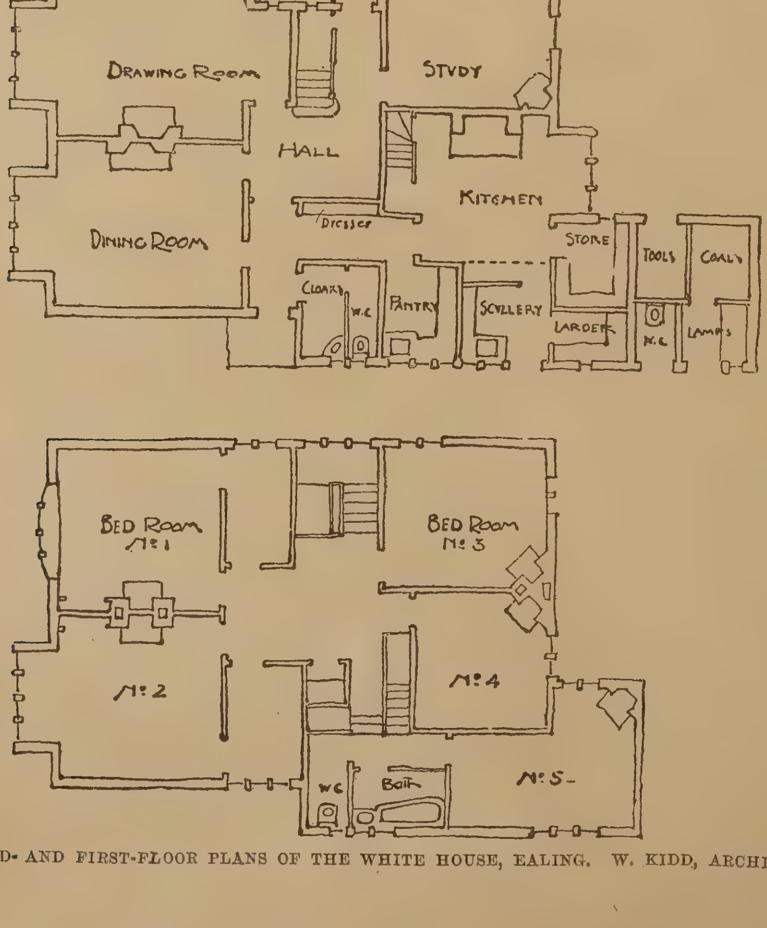
GRECIAN CAPITALS.

A MEETING of the Royal Institute of British Architects was held last Monday evening—Mr. John Slater, B.A., vice-president in the chair. Mr. Alexander Graham, hon. secretary, having announced the decease of Mr. Edward Henry Martineau (Fellow), Mr. Hugh Leonard (Hon. Associate), and Mr. Edmund William Smith, (Hon. Associate), Dr. A. S. Murray, of the British Museum, read a paper on "Two Ionic Capitals in the British Museum." In his opening remarks Dr. Murray said that Professor Meurer, of Rome, visiting the Museum some months ago, identified one of the Ionic capitals in the collection as from the Temple of Wingless Victory at Athens. It was an angle capital from the south-west angle, and was brought over by Lord Elgin, together with some slabs of the frieze. The temple had four Ionic capitals at each end—none along the sides; hence, probably, the later name of the temple, Wingless Victory. The official name was Athena Nikè, which was definitely confirmed some years ago by the finding of an inscription, on marble, in the form of a public record ordering the building of the temple, stating that the designs were to be left to Callicrates, whose name is familiar as one of the architects of the Parthenon. The date of the inscription is agreed to be not earlier than 450 B.C., but not much later—that is to say, about ten years before the completion of the Parthenon. It does not follow, however, that the work had been put in hand at once. There is another inscription added on the same slab obviously some years later, about 430 B.C. Accordingly, between these two dates, 450–430 B.C., the temple had been built. At the latest it is therefore older than the Erechtheum. In the Elgin Room at the Museum can now be studied an angle capital of the Erechtheum side by side with the newly-identified capital of Athena Nikè. The capital of the Erechtheum is exuberant in its beauty; the other is simplicity itself. There is in the museum a fragment of an angle capital of the Ionic Order from the temple at Bassæ by Ictinus, the colleague of Callicrates in the building of the Parthenon. It would be satisfactory if the newly-identified capital could be claimed positively as the work of Callicrates. The Bassæ fragment, however, Dr. Murray considered both simpler and grander in its lines; and there was still the question whether the commission given to Callicrates about 450 B.C. for the Victory temple had ever been executed by him. Incidental reference was made by the author to a curious small terra-cotta capital, archaic Ionic, obtained from Gela, in Sicily, two or three years ago.

He next referred to the Ionic capital from the archaic temple of Diana at Ephesus, described in his paper on "The Sculptured Columns of the Temple of Diana at Ephesus," read at the Institute in 1895. To a large extent this was a reconstruction from fragments of the old burnt temple found under the later one, and fortunately those fragments were enough to enable the reconstruction to be made without recourse to much conjecture. But there remained over some other fragments of capitals from the same archaic temple. As they lay in the museum room they were almost unintelligible. After much doubting he (Dr. Murray) decided to take certain of them in hand, and pieced together the fragments; the result being a restoration, fairly justified by the remains, of an archaic capital of an entirely new character.

There remain two fragments from the archaic temple at Ephesus which the author thought must also belong to a capital, one showing the head of an ox in very high relief; the other, part of his back and haunch, with the tail thrown up over the haunch; if he were right in his assumption, we have thus at least three types of capitals from one and the same archaic Ionic temple. We have also at least three types of bases, and, considering how few are the surviving fragments, no one can say but there may have been other varieties. Pliny says of the later temple that thirty-six of the columns were sculptured. The older temple also had sculptured columns. These enriched columns would be capable of carrying off some variety in the capitals. The moral is that if the architects of the Classical Revival in this country had been aware of the inventiveness of the early Greeks the aspect of our towns would have been very different.

Mr. Hugh Stannus, F.R.I.B.A., then showed and described some photographs of the temple of Athena Nikè and of its capitals which went to prove the identity of the first capital described. Messrs. R. Phenè Spiers, Paul Waterhouse, Beresford Pite, W. D. Caröe, W. Brindley, E. W. Hudson and John Slater also spoke.



GROUND- AND FIRST-FLOOR PLANS OF THE WHITE HOUSE, EALING. W. KIDD, ARCHITECT.

Views & Reviews.

Manchester Cathedral.

There is a sort of incongruity about Manchester Cathedral. The quiet secluded surroundings which we are wont to associate with our cathedrals are absent, and the business premises which take their place repel the visitor and make him wish it were otherwise. Moreover, the exterior of the cathedral is itself by no means imposing, and, without transept or central tower, its appearance is more that of a large parish church. But the great interior, dimly lighted, somewhat compensates for this deficiency, affording many signal impressions and containing details of considerable interest. This book deals with the cathedral in much the same manner as the rest of the same series, beginning with a history of the building and then describing in detail the various features; while the latter portion of it is devoted to the collegiate buildings now known as Chetham's hospital and library, recently the subject of an illustrated article in our own columns.

"The Cathedral Church of Manchester," by the Rev. Thomas Perkins, M.A. London: George Bell & Sons. Price 1s. 6d. nett.

Reading Abbey.

This book will be of more use to the archæologist than to the architect, for the latter will not be much interested in reading about "The Martyrdom of Hugh Faringdon," "The Struggle between the Abbot and the Guild Merchant," the books in the library, and the endowments, revenues, armorial bearings, seals and coinage of the abbey. The dimensions and particulars, however, of the various buildings may prove useful to some persons, but they savour rather of archæology than of architecture. Reading Abbey is to-day an ivy-clad ruin, for "so complete has been the work of destruction that little remains beyond portions of the north and south transepts." The inner gateway is the best preserved portion, and of this we are told that it "forms a beautiful specimen of mediæval architecture in a comparatively complete condition"—though, as the next sentence informs us, "its restoration was carried out in 1861 by the late Sir G. Gilbert Scott, some carvings which had been postponed for want of funds being added in 1900."

"Reading Abbey," by Jamieson B. Hurry, M.A., M.D. London: Elliot Stock, 62, Paternoster Row. Price 15s. nett.

THE BUILDING TRADES IN 1901.

THE building trade during the past year has been very depressed, due to the war, the scarcity of money, and the high price of materials. Speculative house-building has been much hampered, although this does not apply particularly to London and environs. Reports from all over the country record a marked decline in business; and it is doubtful whether much of the work held back early in the year, owing to the high prices of materials and labour, will now be executed. It is strongly felt by employers that the present high rate of wages is no longer justified by the state of trade, but the long notice which has to be served prevents any general attempt to effect a reduction. Leeds employers have, however, submitted a proposal to the bricklayers for an alteration in the winter working time-sheets, the notice as to which expires on April 30th. The Board of Trade memorandum shows that among carpenters and plumbers throughout the country 3·5 per cent. were unemployed in November. In Leeds stonemasons report a slight improvement, but other branches are quiet Employment is fairly good in York and Darlington, but moderate or quiet at Middlesbrough, Stockton, Bolton, Bath and in North Wales; and generally dull on the Tyne and Wear, in Scotland, in Bradford, Huddersfield, Manchester, Liverpool, Nottinghamshire Birmingham and Bristol. In all probability there will in the new year be large migrations of operatives.

England and Wales.

Blackpool.—The borough surveyor of Blackpool (Mr. J. S. Brodie) in his annual report points out that during the past year there has been a reduction in the number of houses erected in the borough, the 370 houses erected showing a decrease of fifty-nine over the previous year. During the year the Corporation instituted legal proceedings for breaches of the by-laws in twenty-nine cases, and were successful in twenty-five.

Colne.—The building trade here is active. The new free library, public hall and technical school is nearly finished. An expenditure of £13,000 for these buldings has been authorised, and the contracts already completed or in progress amount to £10,000. Gas, water, electric lighting, markets and abattoirs are in the hands of the Corporation, and represent a very important part of the town's assets. Under an Act passed in 1897 the town council obtained power to borrow £100,000 for the purpose of improving the water-supply, and £30,000 has already been expended in the purchase of land at Wycollar, where boring operations are in progress. The electric-lighting scheme is approaching completion, and will cost about £39,000. In it provision is made for supplying motive power to the light railway which Messrs. Greenwood & Batley, of Leeds, are about to construct through the town. At the markets during the summer £10,550 has been expended upon extensions. The sewage problem is pressing for solution here as everywhere else, and in the Local Government Board Offices there is at present an application from Colne for leave to borrow £11,000 for bacteria beds. The town council also propose to erect public baths and wash-houses; and a fire brigade station and stables are to be erected. An isolation hospital is also proposed.

Coventry.—The building trade here during the year may be described as quiet. There has been no immediate need of houses. The city engineer (Mr. J. E. Swindlehurst) in his report states that in the eleven months plans were approved of 414 buildings—a number much below several previous years, even when full account is taken of the shorter period; and the buildings completed were 482.

Huddersfield. — Building has been much checked here during the past year by the high wages and costs of materials. No new large buildings have been commenced, and the prospects for this year are not bright.

Hull.—The only work which is keeping firms going is building new premises in the new streets; the erection of four board schools, and the extension of four others; and the work of extension and repairs generally. It is stated on good authority that over 3,000 houses in Hull are unoccupied.

Leeds.—Speculative building fell away at the beginning of 1901, and there is no sign of a distinct revival. In Leeds there have been nearly 2,000 houses erected since January, but this is several hundreds less than in 1900. The number of plans deposited was 3,211. Forty-seven important contracts have been practically finished. Between seventy and eighty big jobs are in hand, including the Roman Catholic Cathedral, the School of Art, the Women and Children's Hospital, several factories and warehouses, an extension of the Corporation electric-lighting works, and churches and chapels, as well as new shop premises and the rebuilding of several hotels. Among the contracts yet to be placed is that for the building of a large engine shed for the North-Eastern Railway Company.

Newcastle.—With the termination of the dispute in the local building trade a great increase of activity set in during the early part of the year, and being continued, the work in the hands of leading firms has been upon a more extended scale than for some very considerable time past. Business premises in the heart of the city, schools and churches on the outskirts, and the steady occupation of the few remaining available sites for dwelling-houses, caused an abundance of employment, and in not a few cases the supply of materials has failed to keep pace with the demand, the result being delay in construction.

Sheffield.—During the past year the building trade has been prosperous. The number of plans deposited with the city surveyor for approval (as complying with the by-laws) has been 1,452. In the preceding twelve months the number was 1,425. There was thus an increase during 1901 of 2 per cent., though the total is practically the same as that for 1899. This year promises to see continued prosperity.

York.—The past year has been active in building operations, and the prospects for this are good.

Scotland.

Aberdeen.—The cutting and finishing of granite in Aberdeen during the past year has, on the whole, shown a marked improvement when compared with 1900. The new century opened somewhat darkly for the majority of the granite merchants, but as the spring advanced a change took place, work steadily increased, and the prospects of further orders are now bright. Most of the leading yards are at present exceedingly busy and, in most cases, have work in hand sufficient to carry them right through the winter. Referring to the home trade, there has been more work done in Aberdeen during the year than in 1900. Perhaps the most noteworthy feature has been the still further development of architectural work in granite. The demand for polished granite fronts in London and the large principal towns has not within the past year been quite so great perhaps as before the outbreak of the war, but nevertheless the local quarries have been unable to cope with the demand for stone for building purposes, while the amount of imported granite used has been greater than ever.

The operative mason trade during the past year has been fairly good, showing, as compared with the previous year, a considerable improvement. On the other hand, the results are far from being up to the standard of 1899 and years immediately prior to that. In the building branch there have been, on an average, between 800 and 900 men steadily employed during the year; while in the monumental branch upwards of 1,100 men received employment. Previous to the end of 1899 the number of men permanently employed in the building branch had also reached to nearly 1,100. The collapse, however, in speculative building accounts for the number having been so largely reduced. Throughout the year the relations between the employers and the operative associations have been of the most cordial character, no dispute of any kind having taken place. The standard rate of wages in the building branch is 8d. per hour, and in the monumental branch 7d. per hour. On these two rates no change has taken place. For the coming year the prospects are good. Unfortunately what is true of the mason trade cannot be said of what might be termed its sister trade—the joiner trade. The year has been a dull one. There was a slight improvement at the term time and throughout the summer, and especially during the past three months, but even now, when work is not so scarce, it is handicapped by the very wet weather which is being experienced. While trade was dull in all branches, especially was this the case so far as building is concerned. This, however, might be accounted for by the fact that the masonwork of many of the larger contracts was not commenced until pretty late in the year. While in December of 1900 there were 842 operatives in employment, at the end of the year the number reached only 700, showing the large decrease of 142 men. The prospects for this year are fairly good. The falling off in the building of tenement houses to some extent contributed to the quiet state of trade, but this was to a considerable extent counterbalanced by the erection of large west-end dwelling houses. Regarding wages, there has been no change in the rate—8d. per hour; and no dispute has taken place between masters and men.

Dundee.—During the past twelve months there has been a gradual abatement of activity in Dundee building trade. There has been little disposition to embark upon purely speculative ventures. The field for enterprise of this kind is, of course, chiefly in the direction of erecting tenement property. Statistics show that about 2,000 houses are unoccupied. Architects, builders and others take a despondent view of the future.

Edinburgh.—There is a gloomy outlook in the building trade of Edinburgh. Many men are unemployed, and there is a lack of important new work in prospect; but, on the other hand, there is a good deal of untouched work for which authority has been asked, and which, no doubt, will be put into operation at the first convenient opportunity. In explanation of the large number of workmen unemployed, it may be suggested that this is a result of the late building boom. Now something like the normal condition of matters has been reached. Speculative work is practically at a standstill, and there are large numbers of unlet houses. In 1900 the number of warrants granted by the Dean of Guild, including minor alterations, was 884, valued approximately at £892,950. These warrants embraced 57 villas, 74 self-contained houses, 225 public and other buildings, 590 alterations, and 82 tenements containing 43 shops and 962 dwelling-houses. In the year up to date there have passed the Dean of Guild 782 warrants for buildings valued approximately at £630,340, a decrease of £199,610 compared with the previous year. This year's programme includes 36 villas, 126 self-contained houses, 148 public buildings, 398 alterations, and 56 tenements of 15 shops and 537 dwelling-houses. More than half the tenements passed during the past year are still unbuilt. The completed work in this department includes buildings for which warrants were passed in the previous year, but not executed until last.

Glasgow.—The building trade in Glasgow has been much less busy than in former years. The trade in cast-iron pipes has been a large one and shows signs of continuing. The light castings trade has, however, not been so good as in the preceding two or three years, and the outlook is not promising.

Johnstone.—The year 1901 in Johnstone has been marked by steady trade progress. Engineering and tool-making have been fully maintained, and the volume of business has borne testimony to the continued activity and trade of Johnstone. There have been about sixteen important new buildings put up inside the burgh. Building prospects are not quite so bright for this year, although several public buildings are proposed.

Kirriemuir.—Building trades still remain dull and lifeless, with but little appearance of improvement. Not a single dwelling-house has been erected in the burgh during the summer, the work done being exclusively confined to the country. It is not that dwelling-house accommodation exceeds the demand. The causes assigned are the want of building-sites, high cost of materials, and local taxation, so that dwelling-houses cannot be erected to pay.

Leith.—A report on the building trade in Leith during 1901 issued by Mr. Beatson, burgh surveyor, states that throughout the past twelve months there was an absence of that briskness which characterised the trade in former years. The prices of building materials reached such a height that the erection of new property, especially tenements by speculative builders, was considerably checked; and though prices have now fallen, it will be some time before this branch of the trade recovers. The prospects of improvement in the building trade are not satisfactory.

Lossiemouth.—The building trade promises to be fairly active this year. Several new public and large private buildings are being commenced, and the supply of dwelling-houses is far less than the demand, even although a considerable number were erected during the past year.

Musselburgh.—There has been a considerable slackening in the building "boom" which has prevailed in Musselburgh for several years past; although the number of applications before the Dean of Guild Court has been larger than usual.

New Patents.

The following patents are open to opposition until February 11th.

1900.—Drain Cleaners.—22,113. G. ROSE, 13, Sussex Terrace, Brighton. For clearing away an obstruction, a spiked cast-iron ball (in two halves) is mounted on the end of a spindle attached to an Archimedean screw, which is rotated by means of a length of rope. Discs of rubber, or brushes, can be attached for the purposes of cleansing the drain.

Lifting Appliances.—22,245. W. R. GREEN, The Retreat, Queen's Road, Peckham, S.E. To enable goods to be handled with safety, a chain or rope barrel is loosely mounted on a shaft and driven through a clutch. Pawls are arranged to hold the load suspended, but instead of being mounted on some fixed part of the framing they are pivoted to a break sheave normally held by a strap or weighted lever. To lower the load the brake is released, allowing the drum and break sheave to revolve together.

Glazing Bars.—22,499. D. J. JARVIS, Humberstone Road, and J. W. WADKIN, 49, Mere Road—both of Leicester; and T. S. KING, 8, Old Heath Road, Colchester. The glazing bar is made of wrought iron covered with lead or other similar yielding material. Flaps are provided at each side of the central web which can be bent down on to the surface of the glass.

1901.—Cement Kilns.—801, J. S. RIGBY, 26, Bagot Street, Wavertree, Liverpool. In order to more effectively prevent the iron or steel kiln body, or its lining, being corroded or destroyed by the action of the heated material or clinker, those parts of the kiln subjected to the greatest heat are cooled by a water jacket; or in some cases the entire kiln may be jacketed.

Double-Acting Saws.—8,737. G. R. PEART and F. FOXON, Union Saw Mills, Charles Street, Sheffield. The saw has its teeth formed in pairs, each facing opposite directions and set right and left. The object is to avoid the sawgate becoming clogged with sawdust and to facilitate sharpening.

The following specifications were published on Saturday last, and are open to opposition until February 18th. The name in italics is that of the communicator of the invention. A summary of the more important of them will be given next week.

1900.—22,780, JARVIS, WADKIN & KING, glazing bars.

1901.—97, BECK (*Sloss*), valves. 517, CANDY, apparatus for treating sewage. 1,382, ALBRECHT, coupling pipes or cocks to mains, &c. 1,631, POCHIN & POCHIN, stone-breaking machines. 2,109, RUELLE & MONTAGNE, smoke-consuming apparatus for furnaces. 2,136, WILD & RIGBY, guard for wood-planing and similar machinery. 2,409, RIISAGER, manufacture of Portland cement. 2,848, SAVAGE, brackets for hanging shelves. 2,928, BENSON, structures of corrugated metal. 3,106, POTTER, floor cramp. 3,777, LIPMAN, adjustable supports for book shelves. 3,896, WILLIAMS, draught and dust excluders. 6,001, DUFOUR, cooking ranges. 10,696, WALLIS & LAGERWALL, roller mills for the manufacture of paint, &c. 18,017 RADCLIFFE & PUGH, joints for pipes under pressure. 20,675, KUNZ, concrete mixing machines. 21,197, DARLINGTON, means for ventilating buildings. 21,463, BEINHAUER, jointing of pipes. 22,809, WICKSTEED, drill rachet braces.

Correspondence.

Alabaster.

To the Editor of THE BUILDERS' JOURNAL.

EXETER.

SIR,—When a correspondent wrote recently, "Where can I procure a good quality of alabaster?" no doubt his query was somewhat ambiguous. But the reply, giving the names of foreign alabasters that are seldom seen or even heard of in this country, was not, in my opinion, satisfactory. None of the fourteen varieties mentioned can be obtained save in disappointingly small blocks and at ruinously high prices; hence none of them find any favour in the eyes of even high-class statuaries, still less in those of builders.

The practical answer to the question is that the alabaster which is used so largely for the interiors of our cathedrals, churches and more important public buildings, is entirely English, procured principally from Derbyshire and Staffordshire. It is obtained in large well-squared blocks (anything up to 22ft. to 25ft. long), and its cost, put on truck at the nearest railway, averages 70s. a ton for the coloured variety and 80s. for the pure white. The latter is somewhat scarce, but is, from its size, infinitely preferable to the Italian variety for all architectural statuary work. The English white is procurable in good, large, economically-squared blocks, whilst the foreign is of all sorts of shapes, never squared at all, and it is seldom that any one of these most disappointing boulder-looking blocks contains more than 2ft. cube, cut them as one may. Where so many suppliers of excellent English alabaster exist, it is somewhat invidious to mention individual quarrymen in this material, but no harm can be done in quoting Messrs. Peter Ford & Sons, of Uttoxeter, and Mr. R. S. Lomas, of 37, King Street, Derby, as amongst the best-known suppliers in the trade.—Yours truly,

HARRY HEMS.

The Eleanor Cross near Northampton.

To the Editor of THE BUILDERS' JOURNAL.

WEST HILL, KETTERING.

SIR,—The Eleanor Cross at Hardingstone, near Northampton, has been undergoing inspection by the Northamptonshire County Council on the occasion of its passing into their possession. The scaffold which has been erected will remain in position for a week or two longer, and an excellent opportunity is thus afforded for measuring the whole structure, provided the weather is not too severe. The County Council would be glad to possess a good set of drawings; and if any student cares to takes this opportunity of measuring a subject which has not yet been properly undertaken, I shall be glad if he will communicate with me as soon as possible.—Yours truly,

J. ALFRED GOTCH.

"Building Construction."

To the Editor of THE BUILDERS' JOURNAL.

DUBLIN.

SIR,—In the article on building construction published in your issue for December 18th the author states that he does not object to criticism. I should like to be enlightened on the meaning of some, to me, strange technical expressions. What is the meaning of a "plat-band arch"? What is the meaning of *raked* rubble masonry? There also appears a quaintness about the expression "purchased" quoins, sills, &c. Surely the builder "purchases" the other materials as well!—Yours truly,

PUZZLED.

"Puzzled" will find "plat-band" in Parker's "Glossary of Architecture" and in Weal's "Dictionary of Terms"; he will also find "plat-band arch" in the Imperial Dictionary (Gresham Publishing Co.)—"(*b*) a lintel formed with voussoirs in the manner of an arch, but with the intrados horizontal." Fig. 82 leaves little room for being puzzled in respect of what is meant by the term; but it seems that "Puzzled" is under suspicion of being the kind of critic excluded in the invitation. If our contributor is to deal with actual buildings he must for each building be local; just now he is Irish, and he is dealing as exclusively as he can manage with hammer-dressed rubble. Owing to the great variety in building stones, it is exceedingly difficult to define hammer-dressed rubble masonry in terms that will apply universally. In the north of Ireland (certainly in Londonderry and Antrim) the term "raked rubble" is used by the workmen. Mr. Smith, from whom our contributor quoted, wrote for the local trade of Belfast. The masons referred to work "whinstone," which is in many respects a good stone; but just because it is a difficult "rubble" stone the men who work it are probably the most expert rubble masons to be found, and it is on this account our contributor referred to their work and gave their name for it. The substitution of Portland cement for rich lime in rubble masonry mortar alters the character of rubble masonry from being a weak masonry to being a very strong masonry, and it is sought to emphasize this. "Purchased" should of course be "punched"; and instead of 22½ bushels to a cub. yd. read 21 bushels.

Manholes and Sewers.

To the Editor of THE BUILDERS' JOURNAL.

GODALMING.

SIR,—Allow me to supplement the information given under this heading on p. 350 of your last issue. The manhole chamber itself at the invert level should be at least 4ft. 6in. by 3ft., and at least 6ft. to the soffit of the arch crown. The shaft from the chamber to the surface need be only 30in. square. If the manhole chamber is circular, it should be of 4ft. 6in. diameter at the invert level, tapering to less above if required.—Yours truly,

J. HERBERT NORRIS.

Engineering Notes.

The Union Offices, Todmorden, are being fitted with the latest improved hot-water heating apparatus by John King, Ltd., engineers, Liverpool, who are employing their "Rahnee" radiators and "Rex" radiator valves.

Municipal Lighting for Norwich.—The Norwich Town Council have decided to purchase the business of the Norwich Electric Lighting Co. The price asked was £19 per £10 share, and the total amounts to about £214,000.

Collapse of a Bridge in Ireland.—One of the tunnel bridges on the Belfast and Bangor Railway fell in recently. Happily the accident was not so serious as was at first anticipated. The bridge affected was near Craigwood. No one was injured.

The Construction of the Cape to Cairo Railway northwards from Buluwayo towards the Zambesi river, a distance of approximately 300 miles, has already been commenced. To carry the railway over the gorge through which the Zambesi flows a short distance below the Victoria Falls a bridge is proposed. Sir Douglas Fox & Partners are the engineers of the railway, and their design for the bridge shows one span of 600ft. in length and at a height of 400ft. above the water. Victoria has a fall of 400ft., and Niagara a fall of less than 170ft.

Electric Lighting at Shrewsbury.—In order to meet the increasing demand for electric light in Shrewsbury, the town council have several times been compelled to extend the machinery during the four years the undertaking has been in their possession. The latest of these extensions has included the erection of a new engine. The new set of machinery is of 350 brake horse-power, and the dynamos are of 242 kilowatts capacity, capable of supplying 4,000 16-candle power lamps burning at one time. The engine was manufactured by Messrs. Bellis & Morcam, Birmingham, and the dynamos by Messrs. Thomas Parker & Co., Wolverhampton. The estimated cost was £2,650, and the work has been done to specifications supplied by the borough electrical engineer, Mr. C. M. Johnston.

BUILDING CONSTRUCTION.

(Continued from p. 336, *No.* 359.)

CARPENTER AND JOINER.

68. FIG. 87 shows a collar-braced roof. The wall-plates, 4½in. by 3in., are bedded on the side walls at the inside face; the wall-plate should be tied to the gables; pieces of old cart-wheel tyres bent up at the two ends should be built into the gables, and the wall-plates should be laid upon them. It is sometimes necessary to tie the wall-plates down by building iron hooks into the walls, the hooked tops of which will catch the top of the wall-plate, but this is hardly necessary for the house we are dealing with. The usual spacing for rafters, joists, &c., is 1ft. from centre to centre. A rafter is placed over the gable to be within, say, 6in. of its outer face. The drawing shows the rafters as running from the outer face of the side wall where they show to the ridge-piece; they are spiked to the wall-plates and to the ridge-piece. Care is to be taken that the ridge is level and that the roof surfaces are true and without twist. Twist is easily detected by looking along the top edges of the placed rafters; the ridge-piece is 9in. by 1in., and the rafters and collars are 4½in. by 1½in. The collars are nailed on, and care is taken to have the bottom edges of the collars all truly level and in one plane—they are to serve for ceiling joists. The collar braces should be lightly sunk and shouldered to the rafter (about ¼in.); the rafter should not be sunk for the brace. A collar-brace acts as a strut if the feet of the rafters are fixed, but it is a tie if it is depended upon to prevent the roof spreading. We have provided for tying the wall-plates to the gables; the lengths between gables are short, 11ft. and 9ft.: having regard to the tying of the rafters together with the "battens" and the lathing and plastering for ceiling, it may be assumed that the feet of the rafters are fixed. Where the distances between gables are greater I use strap-iron bracing on the rafters, one V-shaped brace having its ends near the ridge; the point of the V may come as near to the eave as ever we like. The ridge-piece helps the battens to sustain the thrust (taking the side of the roof to be a girder). The brace is fastened to each rafter with a screw. This is not a usual mode of strengthening a roof, but if followed it will be found to be effective.

If the stress on the collar-brace is a thrust, there is is no need to sink the rafter for a dovetailed end on the brace; and if it is a pull the rafter should not be weakened at this point; in neither view is it wise to sink the rafter. The braces are well nailed against the rafters and the nails clenched. Fig. 87 shows a rafter in position, with cross-sections of wall-plate battens 3in. by 1in., and ridge-piece. Battens are sometimes only ¾in. thick, but this is a mistake; they should be not less than 1in. thick, to give sufficient hold for the slating nails.

The student should note that the word "batten" also means a piece of timber 7in. wide, as distinguished from "deals" 9in. wide and "planks" 11in. wide. In some places slater's battens are called slater's laths, and similar things are called laths when used to support tiling. Again, when battens are employed to carry laths to support plaster free from the walls, they are in some places called "studding" and in other parts "stoothing." ("Stoothing"—which I once saw put as a question, "What is stoothing?"—appears to be a local way of pronouncing "studding.")

The rafters being set up spiked to wall-plates and ridge-piece, the slater's battens are nailed on to the *gauge* of the slates to be used, having also regard to the commencement at the eave and finish at ridge. The nailing-on of these pieces is where the carpenter and slater meet—is it the work of the carpenter or that of the slater? I believe it to be the work of the slater, because he is responsible for the lap of the slates, and this is determined by the length of the slates and by the gauge to which the laths are put on.

The rafters for the lean-to are spiked to wall-plates on both walls, as shown. A small beam, 7in. by 3in., 9ft. 6in. long, will carry the shed eave.

The floors of the bedrooms are of ¾in. flooring boards on 3in. by 1½in. joists; the joists are laid on the concrete, kept ½in. over it by 1in. by ½in. laths, placed about 4ft. apart. The joists having been spaced (1ft. apart centre to centre) and levelled, keep them in position by tacking a board temporarily across them; the joists to run the long way of the floors.

The timber for these houses will be supplied altogether from spruce (white) deals, planks or battens.

69. The flooring boards are not tongued and grooved; they are of batten width. The lengths are so short that there will be very few beading joints, and they will be "square" (Fig. 88). Care must be taken before ordering timber of all kinds to study the sizes, so as to have as little waste as possible. The lengths of spruce deals, &c., in the yards appear to be in even numbers of feet; as, say, 8ft., 10ft., 12ft., 14ft., &c., up to 20ft. Enquiry must be made of the merchant from whom it is intended to buy as to what he has, and the quality should be examined. Sometimes it will be found necessary to sacrifice some timber as waste for the sake of getting a better quality than is to be had from more economical lengths. It is advisable to lay the boards with their joints as tight as possible, and for this purpose a pair of flooring cramps may be used. A board is nailed down along the wall, say, of the outer gable (the boards are supposed to be jointed, cleaned and thicknessed; if flooring boards are of different thicknesses the floor will be irregular). Two or three boards are next laid down to continue the floor from the first board, the flooring cramps are made fast to a pair of joists, a straight strong piece of timber somewhat thicker than the boards is laid along the outer edge, and the cramps are tightened up against it, pressing the boards tightly together so that the joints are quite close. The boards are then bradded down (using two 2½in. brads in each board at each joist, driven at about an inch from the joint). The brads should be driven well home, if necessary punched. I do not give a drawing of these flooring cramps. The student should examine the actual tool, notice the clutch action by which it is jammed on to the joist, and the "lifting jack" gearing by which it presses against the boards to be tightened up.

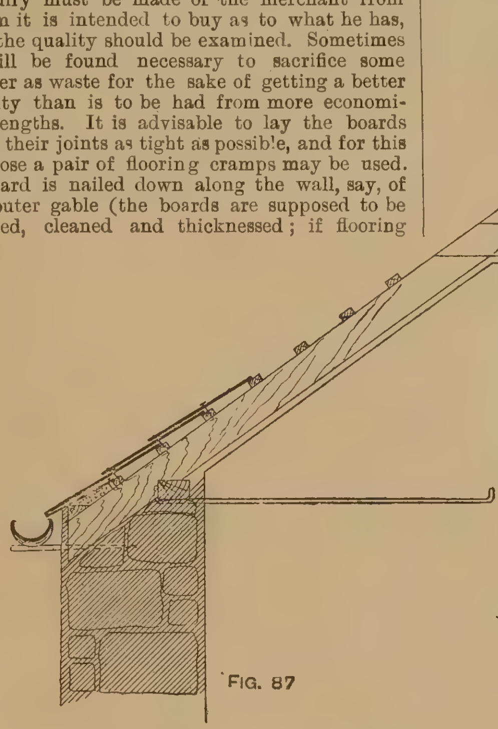

FIG. 87

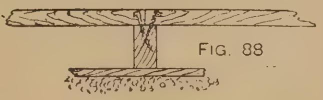

FIG. 88

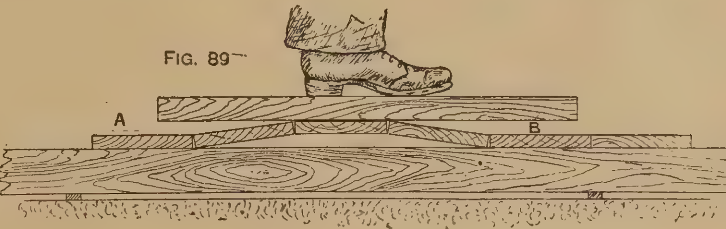

FIG. 89

Toolmakers publish catalogues with very good illustrations of the tools they make or sell; there is usually no great difficulty about getting copies of these catalogues. A great advantage modern architects have over their predecessors is in these numerous well-produced pictorial catalogues. There are doubtless many worthless things invented, and their sale pushed by catalogue advertisement, but the architect is not thus taken in to any great extent. It is a good plan to preserve and file good catalogues: the larger bound catalogues are in almost every-day office use. The firms which at great expense produce and send out these things have no objection (indeed, they much desire it) to their catalogues being intelligently used. Good catalogues should be treated with respect, though many of them are to be had for the asking and many are sent without our asking for them.

Cramps cost from 10s. to 15s. each. These small floors may be laid without cramps by what is called the method of folding (Fig. 89). The board A is nailed down at a distance from B to allow of some tightening; the intermediate boards are placed in position as shown, and the carpenter by his own weight and otherwise presses them down, as shown, when they are bradded to the joists. It is too often the case that the boards of ground floors have joints which remain tight owing to the damp ground which these floors cover. Dampness of site is a much more serious matter in the country than in towns, where the general surface is practically roofed over by macadamized and paved roads, flagged footpaths, yards, &c., and the rainwater is carried off by numerous drains. A point on which I shall no doubt repeat myself over and over again is:—Much of the dampness showing on walls does not come through the walls, but merely shows there because, owing to the damp ground sending its moisture up into the space included within the walls of the house, this space is "saturated"; and at all times when the temperature of the walls is lower than that of the air, moisture condenses upon them. This is the reason why, during a thaw, the walls stream with water. Owing to the concreting of the site of these floors the joints will open, because the boards will dry; there will be sufficient ventilation of the timber through these open joints.

Doors.

70. The front door (Fig. 90) is framed and staved (or framed and filled). The door frame is rebated in the solid, and is set upon door-blocks. The function of the door-blocks is to raise the wood of the door-posts above the ground, because door-posts decay more rapidly at the

ends next the ground than higher up. It is necessary to hold the door-posts fast at the bottom, to prevent them closing. This is sometimes done by sinking a shallow pit in the top of the door-block, to take a short tenon on the post, but it is better to ring (R) the ends of the jambs and drive a spud S (Fig. 90). The ring prevents the post splitting with the spud. The spud enters a hole in the door-block, where it is made fast with some Portland cement. Note—the ends of the posts should be well soaked with drying oil and whitelead paint sometime before setting them on the door-blocks; and because fresh cement in contact with oil-paint turns the oil to soap, it is advisable to prevent the cement used to fix the spud touching the painted end, by putting on a piece of thin Willesden paper like a washer. This is a substantial door, having a head and four bars; it is without bracing. The hinges are three in number—heavy 4in. butts. The door is fastened with a good heavy thumb-latch and a serviceable wooden-cased stock lock. A very great number of the iron thumb-latches made for sale are flimsy and quite unreliable (Fig. 91). The old thumb-latches made by the local blacksmith were strong. It should be remembered that, a door is expected to latch itself when banged to; doors willbe banged, the wind will do it, and they are expected to stand it. The catch A is too trifling, the slope is too steep, and the latch is either bent or the trifling guard B is burst off. The old blacksmiths gave a good long catch A′ with a gentle slope, over which the latch slid without too much friction. The number of latches with slight differences is bewildering; there are many of them bad. Let the student examine the catalogue of a good firm and choose a pattern once for all, and as often as he can let him use this pattern of latch. The plate to which the catch A is riveted is usually too slight, and it will not stand against a good push from without. The student should take a stock lock to pieces, thoroughly examine it, and understand its action. The lock should be fastened to the door with $\frac{5}{16}$in. bolts, and the keeper should be well secured to the door-frame.

The other doors are ledged doors without bracing; such doors had better *not* be fitted to the inside size of the door-frame and the door-frame slipped; they are more satisfactory made to lie against the door-frame (Fig. 92). In this way they have more freedom to "cling" slightly without showing bad fitting. The front outside door (Fig. 90) is to have $2\frac{1}{8}$in. by $4\frac{1}{2}$in. framing top and sides; the bars are $1\frac{1}{4}$in. thick, of the widths shown; and the staving, which is to be tongued and grooved, and let into sides and head, is to be $\frac{7}{8}$in. thick (finished); the joints are to show $\frac{1}{2}$in. beads outside. The other doors are to have 1in. ledges, the sheeting to be $\frac{3}{4}$in. (finished) tongued and grooved; to show $\frac{3}{8}$in. beads both sides; to be well nailed together and the nails properly clenched. They are to have hook hinges, good thumb-latches, and

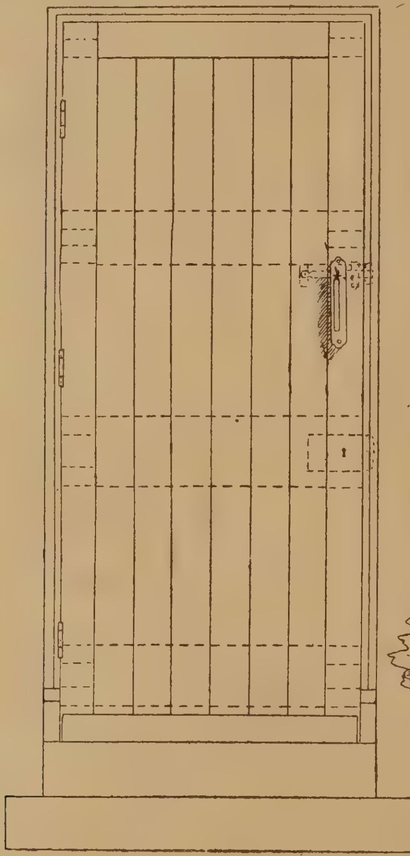

FIG. 90

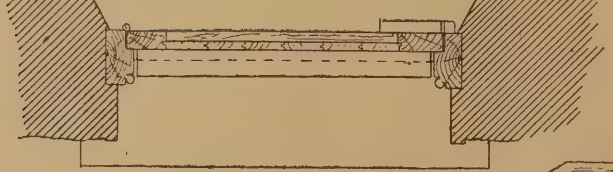

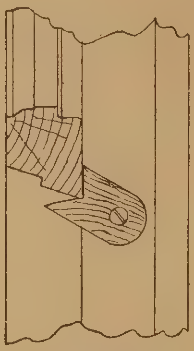

FIG. 98

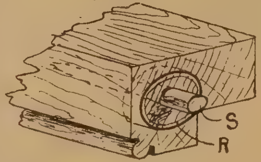

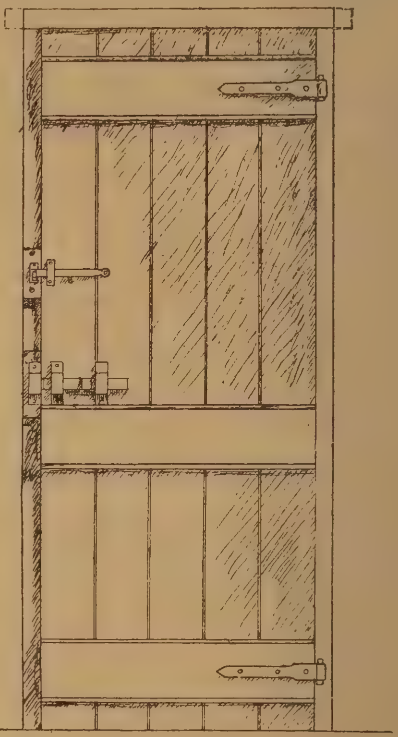

FIG 92

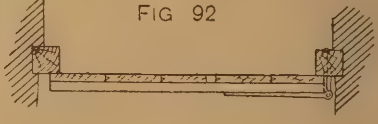

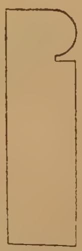

FIG. 95

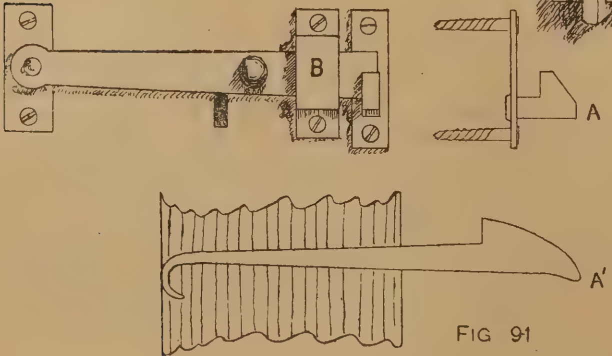

FIG 91

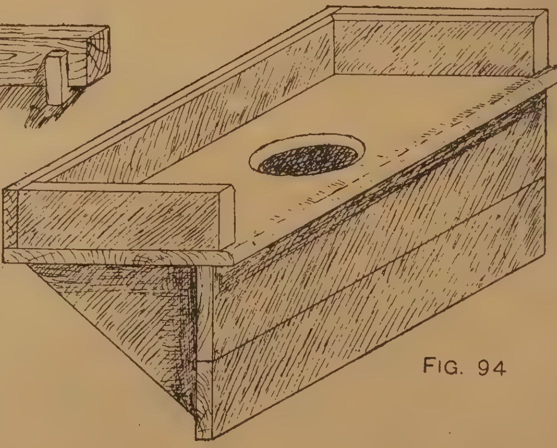

FIG. 94

fastened in every case inside with wooden bars (Fig. 93).

Partitions.

The plan (Fig. 81) showed a partition between the outside door and the kitchen fire. This partition could be brought a little nearer the door with advantage, giving a little more room at the fire, and the outside door should open against the bedroom door. The partition may be made to stand 7ft. over the floor level; it should have a 3in. by 3in. end post, which should be fastened to the outside wall by a cross-piece. If the funds provided would allow of a top to this small hall-way and a second door to the kitchen, the comfort of the labourer and his family would be considerably promoted. As the drawing stands, I would run four bars 3in. by 2in. from the 3in. by 3in. post to the inside gable wall, and on these I would nail ¾in. tongued and grooved matchboarding let into a sleeper 3in. by 2in., having a ¾in. by ¾in. rebate to take the ends of the boards spiked to plugs let into the concrete floor. The upright post should be let into the floor. The bedroom floors should have 4½in. by 1in. skirting, with ½in. bead outside top corner well fastened to plugs, and put on with respect to the finished plastered surface of the walls (Fig. 95).

The privy seats should be made so that they may be lifted out to allow the privy pit to be properly cleansed and to allow the seats to be cleansed and disinfected if necessary. The seat and riser should be made fast with proper brackets, and the seat should rest on pieces properly made fast to the side walls (Fig. 94).

71. There is some difficulty about giving a cheap window that will be satisfactory. It should be weather-tight; it should be available as a ventilator; and it should be easily kept in good order. (*a*) The bottom sash may be fixed, and the top sash may be hinged and allowed to fall back with a quadrant fastener (Fig. 96). (*b*) The sashes may be sliding guillotine sashes having either half fixed and the other half hung with cords, weights, pulley-boxes, and having sash-fasteners. (*c*) Both sashes may be hung. (*d*) The sashes may be hung without weights, one sash balancing the other in a way I have made much use of (Fig. 97). When two sashes are hung on the same pair of suspenders, if the suspenders are too short when the top sash is up the lower sash will not be down upon its sill; if the suspenders are too long when the lower sash is quite down the top sash will not be up. It is therefore necessary, if this mode of hanging is to be successful, to have a means of adjusting the suspender to be exactly of the right length. Fig. 97 shows the pulleys and suspenders which I employ for this kind of window. I have had several hundred sets made specially for me by Messrs. Colledge & Bridgen. They are perfectly satisfactory, but the cost is rather too great; possibly, if they were more generally used, manufacturers could afford to supply them at a cheaper rate. The adjusting screw is at A. For suspenders I have hitherto used Hookham's steel ribbon sash line to fasten the ends. The ribbon is brought through the eyes, it is turned up, bound round with a few turns of tinned-copper binding wire (used by electricians), and the turns of binding wire are soldered together.

Fig. 98 shows a very simple ingenious catch for holding up an unhung lower sash in primitive times, when hanging and parting slips were not thought necessary for windows. Another ingenious old-fashioned catch for holding back an outside hinged shutter might be noted; the hole in the catch is square, and the hook on which it works has a square shoulder, with a round spindle above, which allows it to be turned when lifted above the square (Fig. 99).

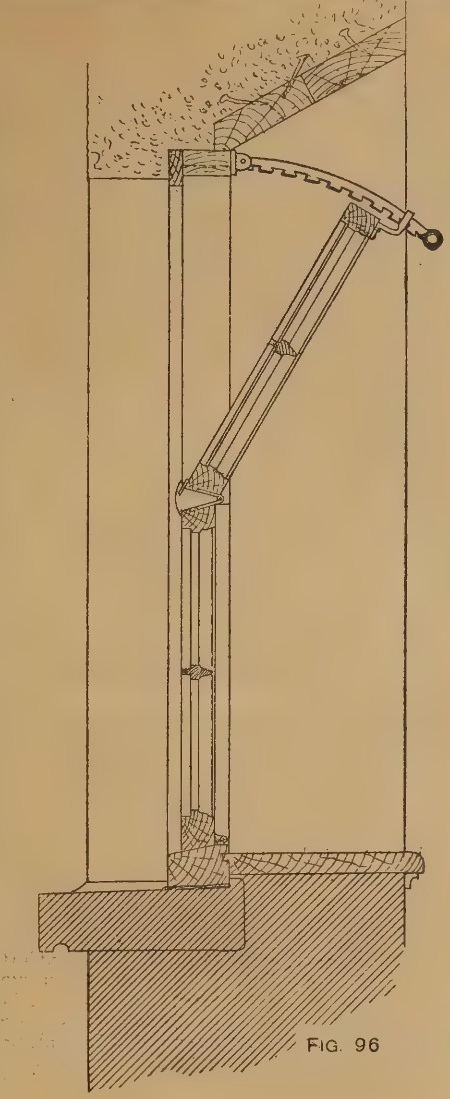

FIG. 96

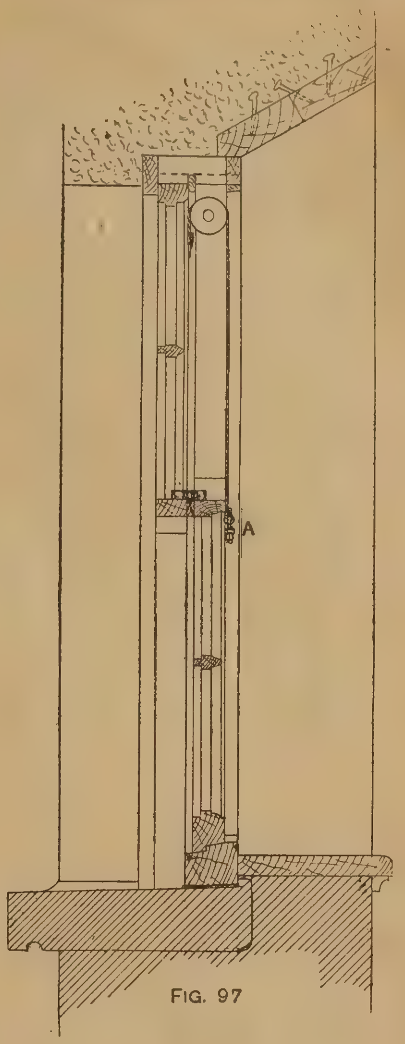

FIG. 97

Architectural students who take an artistic interest in old buildings should note also any mechanical arrangements of this kind which our ingenious predecessors put in common use.

The doors of these houses are not given as model doors. The windows are not to be taken as model windows.

I reserve the general question of windows for the present. The kind of window which can be afforded for these houses is shown at Fig. 96.

Slating.

72. I shall suppose that the rafters are all properly fixed, and that the top edges are all truly in one plane for each side of the roof. The size of the slates is "Countess," 20in. by 10in. Slates of various lengths cannot be mixed in any course. Each course must be of slates all of the same length; but slates may be used of different breadths in the same course if care is taken that the edge joints of two successive courses do not come too nearly together. If slates of uniform length and breadth are used over the whole side of any roof, the bands between the lower edges of successive courses are all of the same breadth, and the edge joints of alternate courses lie in the same straight lines from eave to ridge, the perpends are right. With slates of uniform size the slater has less concern than he would otherwise have. In this case, when he has got his double course at the eave settled, the distances between the battens are the same all the way up to the ridge. Slates are of many different sizes, as should be expected if it is remembered that they are stones which are quarried. Bricks are made of various sizes, but common building bricks are nearly of the same dimensions; the size of common bricks appears

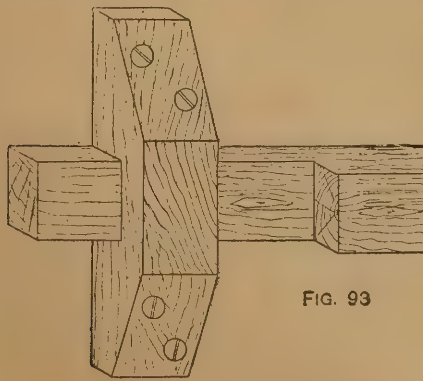

FIG. 93

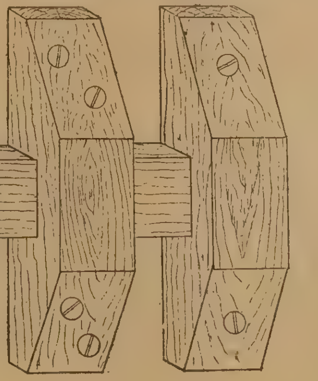

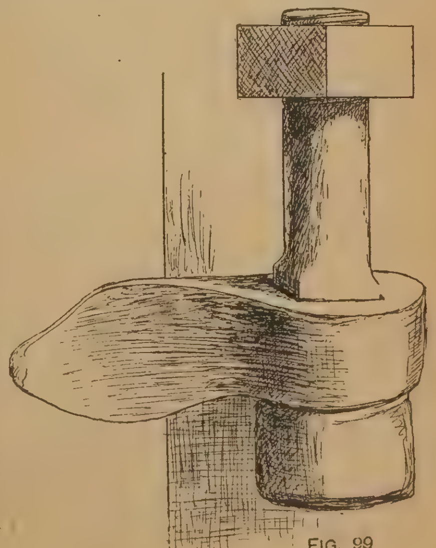

FIG. 99

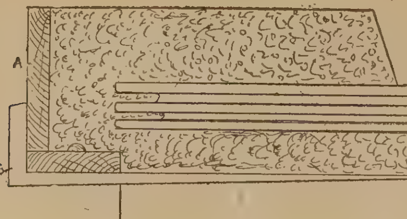

FIG 100

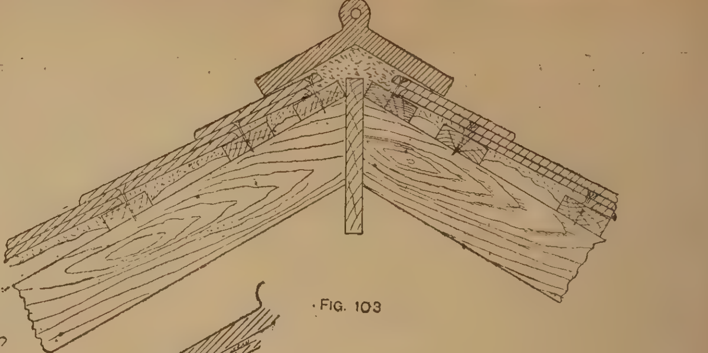

FIG. 103

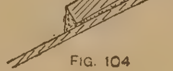

FIG. 104

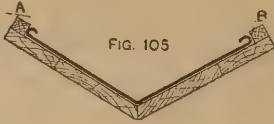

FIG. 105

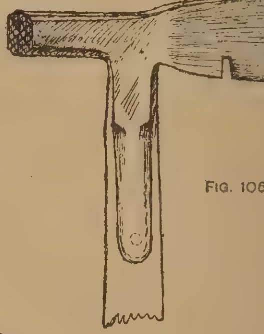

FIG. 106

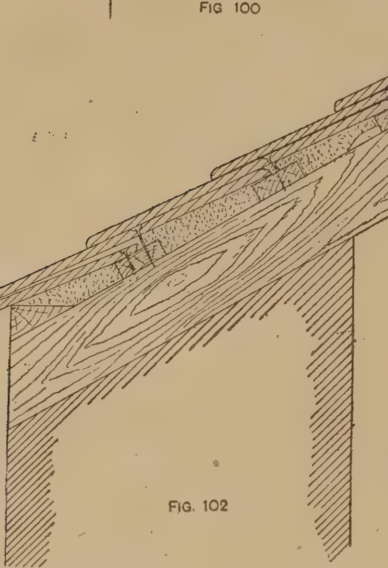

FIG. 102

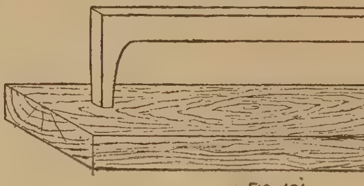

FIG. 101

to be that most convenient to meet the various conditions of manufacture and handling; the sizes of slates are necessarily various, just as stones quarried from natural bedding and jointing are various in size. In this country in the building trade slates of different sizes are given special names which are not of much assistance. Examinees are sometimes asked the sizes of "Ladies," "Countesses," "Duchesses,"&c. In some quarries twenty-six different sizes are supplied; it appears to be an unreasonable burdening of the memory to remember the names for all these sizes. The smaller sizes are sold by the M, which, so far as we are concerned just now, means 1,200 (dealers get an allowance from quarry owners for breakage, over 1,200), and the large sizes—"Imperials," 30in. long, "Rags," 36in. long, and "Queens," 36in. long—are sold by weight, by the ton. The slater goes over the slates as supplied; he tries them with his square across the tail (the dressed end which will be the bottom end), he tries them for size, and he dresses them to square and to size if they require it. When the slate is dressed it is gauged for the nail holes; the position of the holes is marked with the pick of the zax and the holes are made, and the prepared slate is set up in front of others in a similar condition. The slates are also examined for flaws, and unsound slates are set aside—if there are an unreasonable number they should be returned to the dealer; a few may come in for fraction slates at gables or barges, or at chimneys and skylights.

Slates are dressed by means of a tool called a *zax*; it is a blunt knife, with a spike, which stands up from the back about the middle of the length. The slate to be dressed rests on an iron straight-edge at the line to which it is to be dressed. A slater will sometimes use for the edge a heavy slate set on end. The bed of the slate is held uppermost in dressing, with the result that the edge next the bed is sharp, the other edge being roughly bevelled from the flaking of the slate; the holes are also driven from this side, and there is produced a rough countersinking on the other side.

Tilting fillet (Fig. 102).—It will be seen on examining a section of slating that there are three thicknesses of slates over any batten, but there are only two thicknesses at the face of the wall at the eave. If a common batten is nailed along the rafters, a slate resting upon it and upon the next batten would be parallel to the rafters, but the slates are not parallel to the rafters; it is, therefore, necessary to have something higher than a batten—this is called a tilting fillet. This tilting fillet is usually made more than the thickness of a slate higher than a batten, to give the slating what is called a "bell cast" at the eave. This makes the slates near the eave bear close at the tails, and it has some value in giving extra security here, giving better catch for the rendering inside and closing tighter against the wind outside. When it is necessary to cut a slate, the slater makes a line of holes with the spike of his zax, and along this line the slate easily divides.

A row of "half" slates 11½in. is put on, having the proper projection for the eave, say 3in. These "half" slates have their *beds* upwards; and each has a pair of holes in the head (driven opposite to the usual way). They rest on the tilting fillet and on the first batten, to which they are nailed; they are bedded on the "beam filling" in a full bed of mortar. The slates are holed so that the first row of slates—to show—are nailed near their middles to the first batten, their tails lying flush with the tails of the half slates and thus forming the slate eave. Care must be taken to break joint with the half slates. The portion of a slate which shows on the roof is called the "margin." If the battens are properly spaced to the gauge of the margin, with ordinary attention in nailing the tails of the slates will be in a straight line (battens should be the distance of the gauge *less the breadth* of a batten apart) and the margins will be all alike (with uniform-sized slates). In nailing slates near the middle great care must be taken (especially where the slate does not lie solid) not to drive the nail too far so as to put a strain on the slate (there is no danger of this kind where slates are nailed by the heads). The lap of a slate is the distance of the tail from the holes in the slate next beneath it. The slater should measure his rafter carefully to see whether he will, with the given lap, have any waste at the ridge, and he should increase the lap so as to have as little waste at the ridge as possible. The nails for this job will be 2½in. iron nails, warmed to thoroughly dry them, and dipped in boiled oil. The battens extend to within an inch of the faces of the gables. In slating up the barges a mould A (Fig. 100) is set up on iron hooks B, the slates are bedded in cement-mortar, which is allowed to take the shape of the mould and made to enclose the edges of the slates. When the slating is carried up to the ridge this barge will be completed in smooth-surfaced concrete as shown. This makes a secure and watertight finish to the barges. Just as the carpenter and slater meet on the question of nailing battens on the rafters, so the duties of the slater and plumber overlap in the question of flashings and valleys; and in finishing the barges, rendering and setting the ridges, he does work that might be claimed for the plasterer and mason. The general dressing of the slates is done on the ground, but there may be minor work for valleys, chimneys, &c., that is best done on the roof; for this purpose he will require a small "hard" or straight edge set on a small wood block (Fig. 101), and a light handy zax. Many slaters use a plasterer's lathing hammer (Fig. 106) for nailing battens and slates; the regular slater's hammer will be found more useful for repairs; slates may be holed by it, and any small dressing may be done with the trowel.

The sheeting for the valleys should be done by the carpenter. Lead should not be anywhere fastened with nails. If the sheeting is nailed to the rafters, as in Fig. 105, and the curbs A B nailed so as to make the distance A B wider at the top than at the bottom, the lead will not slip downwards. The lead should be cut, dressed and put in position by a plumber; the plumber should also cut the soakers, aprons and covers for flashings. Fig. 103 shows a cross-section of the ridge showing a roll-ridging. A very common error in some localities is to finish ridging with a pointing of cement drawn against the edge of the ridge-tile (Fig. 104). This is a vicious practice: the pieces of pointing soon break off and rattle down to valleys and into eaves-gutters. The ridge-tiles should be set on a bed of cement-mortar. The joints should be wide enough to allow this mortar to reach the surface, where it is cut off flush and smooth; a light bedding is sufficient along the edges, where the surplus should be cut off clean and flush. The slater having placed the soakers, the plumber will fit the covers in the raglets, and fix them with a few lead plugs; the slater will fill up the raglets to the lead with cement-mortar, and finish the joint smooth. In working with cement-mortar for these purposes, the slater must be very careful not to stain and smear the slates. Such work must be done in weather when there is no danger of rain coming before the cement is set to wash it over the slating. The slating is now to be rendered inside with good well-haired plasterer's coarse stuff. The stuff for this purpose will be improved by the addition of a proportion of Portland cement; it should be wel pressed into the spaces between the rafters and the slates and between the battens and the slates. The proper rendering of slates is of great importance; it properly beds and supports them and it prevents them rattling with the wind (it may be observed that the holes in old loose slates, iron-nailed, have become large enough to let the heads of the nails pass through, occasioned by this rattling). Zinc and copper-slating nails are cut by slates which move with the wind. Galvanised iron nails are probably best for slating.

(*To be continued.*)

BABYLON.

THE GERMAN EXPLORATIONS.

THE work of exploring the vast tumuli of "great Babylon," says a writer in the "Daily News," has at last been undertaken by an expedition organized by the German Oriental Society, under the direction of the able architect, Dr. Rober Koldowey, and a staff of Assyriologists. The work was commenced upon the great mound known as the "Kasr," or "palace," a tradition which the researches have confirmed, for here has been found the great royal residence of Nebuchadnezzar the Great (B.C. (604–561) and his successors. The most important discovery made as yet is that of the royal banqueting hall, or throne-room, a vast chamber 120ft. long and 60ft. broad, and which had once been richly-decorated with painted stucco, as described by the prophet Ezekiel.

There is every just reason to suppose that it was in this chamber the fatal last banquet of Belshazzar was held, when the corridors leading to it echoed to the tread of the advancing soldiers of Gobyras, the general of Cyrus, and on that night (Tammuz 16th, B.C. 538) the first of empires fell.

Leaving this chamber and passing without the palace ruins, still more interesting discoveries await us. On the east side of the palace were found the remains of a stone-paved broadway. This terrace was about 80ft. wide, and has been excavated for a distance of about 420ft., and the direction being ascertained, the termination was found near the south-east corner of the mound, making a total length of about 1,400ft., or over a quarter of a mile. It may well be compared with our Parliament Street, for at one end was the royal palace, like that of Westminster, and the sides were flanked by royal residences, temples and Government buildings. Below, on the west, were the royal grounds, and beyond those the "great river Euphrates." The whole length was paved with blocks of breccia of a reddish colour, no doubt originally laid in some design, but now displaced. The limestone blocks are the largest, being about 1yd. square and 1ft. thick. These massive blocks were laid on a brick foundation and fixed with bitumen. But they are no silent stones, for their surface tells an ancient story, for each is inscribed, the larger with the words: "I am Nebuchadnezzar, the King of Babylon, son of Nabupalassar, King of Babylon. The highway of Babylon for the Procession of the great Lord Merodach, with blocks of stone, the product of the mountains (limestone), I paved the street. May the Lord Merodach with everlasting life endow me." Built probably about the middle of the great king's reign—say about B.C. 580—few streets have been associated with so many epoch-making events as this Babylonian sacred way. Being the main way of access to the palace it would be the thoroughfare along which all the great pageants and royal entries passed. Some of these were epoch-making in their importance.

"The Famous Houses of Bath and District."—Messrs. Meehan announce the publication of this book by Mr. J. F. Meehan, with an introduction by the Marquis of Dufferin and Ava. It will be full of literary and other recollections. The illustrated articles on the mansions in the district include Longleat, Badminton, Dyrham, Fonthill Abbey, Ashton Court, Shockerwick, Bathford House, Kingston House (Bradford-on-Avon), Queen Charlton, Glastonbury Abbey, Montacute House, Clevedon Court, South Wraxall, Draycott and others. The edition will be strictly limited to 500 copies, and the price to subscribers will be 10s. 6d.

Keystones.

A Statue to Renan is to be erected in Tréguir, his native town.

A Bust of Falguière, the sculptor, is to be executed to the order of the French State by M. Marqueste, the Academician. The bust will be placed in the museum of Versailles.

At the Agricultural College, Cleobury Mortimer, Salop, extensive additions are being erected by Mr. H. Dorse, contractor, of Cradley Heath, Staffs.

Messrs. Gordon & Gunton are the architects whose designs have been adopted for the erection of office buildings and coal stores at the Hackney Electricity Works.

New Cottage Homes at Evesham have been built by the guardians at a cost of £1,650. Mr. H. S. Harvey was the architect, and Mr. William White, of Hampton, the builder.

The will and two codicils of the late James Brooks, F.R.I.B.A., have been proved by his son, Mr. B. C. G. Brooks, and Mr. E. F. Cross (of Sidcup), the executors. The value of the estate was £5,771 7s. gross and £3,939 16s. 11d. nett.

Truro Cathedral.—The cracked bases of the nave pillars in the new part of Truro Cathedral have been inspected on behalf of the committee by Sir Thomas Drew. When he has worked out his calculations he will prepare a report, which will be made public by the committee.

Charles Boulle was one of the great French cabinet-makers of the eighteenth century, and his fellow-craftsmen of the Faubourg Saint-Antoine, who strive to carry on the traditions of the older masters, are about to organise a movement for the erection of a statue to the famous *ébéniste.*

The London Drawing and Tracing Office Calendar for 1902 is embellished with a coloured representation of a nymph who is evidently of an architectural or engineering turn of mind, for she holds a pencil in one hand and a compass in the other. Readers should send for one of these calendars to 98, Gray's Inn Road, W.C.

A Stained-Glass Window in Memory of Queen Victoria has been placed in St. Mary's Church, Kettering. The window consists of seven lights. The central three are The Crucifixion, St. Mary, St. John; and the four outside lights: St. Peter, St. Andrew, St. Philip, St. Paul, the patron saints of four Kettering parishes. In the tracery at the top is the figure of St. George. The whole was designed and executed by Messrs. Percy Bacon & Brothers, of 11, Newman Street, London, W.

The Ancient and Extensive Kitchens of Holyrood Palace, in which nothing has been cooked since the days when Prince Charles Edward held his brief Court in Edinburgh during the "Forty-five," are now in the hands of workmen, and, together with the rest of the palace, are undergoing complete restoration. Up to the present the cooking for the High Commissioner's entertainments at the time of the General Assembly has been done at one of the large hotels.

Mr. David Law, the eminent etcher and water-colourist, died recently at Worthing. At an early age he was apprenticed to a landscape engraver, but finding landscape engraving losing popular favour, Mr. Law, in 1851, accepted an appointment in the Ordnance Survey Office at Southampton as a map engraver. After years of patient labour in this field the artistic instinct reasserted itself with irresistible force, and he left the public service to follow the career in which he gained such distinction.

A New Reredos at St. Endellion Church has been erected at the east end in place of the sombre and time-worn hangings behind the altar. The new oak reredos is a memorial of the late Queen Victoria. Gothic in style, it consists of a large centre niche, plainly backed, with a niche on each side filled with panels or squares, carved with delicate Gothic tracery. Dividing the niches are bold columns, patterned with spirals of acanthus, and bearing caps with shield reliefs. Each niche has a canopy. Panelling with a light open-leaf cresting, covers the chancel wall to the right and left of the reredos and up to its full height. The sanctuary has been further improved by having a substantial raised oak floor.

A New Technical Institute at Belfast is to be erected at a cost of about £100,000 by the Corporation of Belfast.

Mr. William Jacques is the architect for the erection of two blocks of buildings in Carter Road, Plaistow, for the West Ham School Board.

Wolverley Grammar Schools, near Kidderminster, are undergoing alterations from plans by Messrs. Meredith & Pritchard, architects, of Kidderminster. Mr. H. Dorse, of Cradley Heath, Staffs, is the contractor.

Americans and the Ecole des Beaux-Arts.—A group of American architects, grateful for the benefits derived from their study at the Paris School of the Beaux-Arts, founded a series of prizes to be awarded to students in the architectural section of the school. MM. Nicod, Danis and Hubaine are the successful competitors this year.

A New Hotel at Doncaster is to be built at the corner of Bridge Terrace and Hexthorpe Road, Doncaster, for Messrs. Hewitt Brothers, Ltd., brewers, Grimsby. The contract for its erection and for pulling down the property at present on the site, a portion of which is required for street improvement, has been secured at about £2,000 by Messrs. Mullins & Richardson, builders and contractors. The architect is Mr. Athron, of Market Place, Doncaster.

A Statue of the Great Sculptor Carpeaux is to be erected in his natal town of Valenciennes. M. Félix Desruelles has been chosen to execute the work. The idea is to represent the figure in working smock standing on a scaffold surrounded by a "vision" of the "Danse" and the "Cinq parties du Monde." The sculptural effect will be somewhat reminiscent of the famous atelier de Carpeaux by Maignan in the Luxemburg Museum.

Subsidences in the City.—Some anxiety is being manifested by owners and occupiers of properties in Finsbury Pavement in consequence of the cracks which have appeared not only in upper floors but in basements. In several cases the movement has assumed serious proportions, and the inference is that the settlements are due to railway works beneath the thoroughfare. Surveyors acting on behalf of property owners and the railway companies are drawing up reports on what has taken place. One of the buildings that has suffered extensively is the Moorgate Street Station of the City and South London Railway.

A New Fire-Station is being erected for the Fire Brigade Committee of the London County Council in Euston Road. The land has cost £7,700, and the contract for building amounts to £14,377. The builders are Messrs. Simpson & Co., and the supervising architect is Mr. W. E. Riley. The new station is to be an imposing building in Portland stone and red bricks. Ample provision will be made for the third officer's quarters, and quarters for the station officer, seven married men, coachman, and single men; and there is to be a large recreation-room. Stabling will be constructed for six horses, and the engine-room will be 39ft. by 33ft., with space for a horsed escape, steam-engine, and hose cart.

A New Training School for Seamen.—The Admiralty and the Home Office having condemned the industrial training ship "Formidable," stationed at Portishead, the managers of that institution are now contemplating the erection of a shore school at an estimated cost of £30,000. They have in view an eligible site, and are only awaiting assurances of support from public authorities before proceeding in the matter. The "Formidable" has been stationed at Portishead for thirty-two years, and during that time about 3,300 lads have passed through the school, of whom 2,100 have found their way into the merchant service and the Navy, the remainder going to situations on shore and emigrating. The annual cost of maintenance is about £7,000 or £8,000 and is mainly derivable from grants by the State, school boards and other authorities. It is proposed to build the proposed shore school after the pattern of the naval institutes at Portsmouth and elsewhere, with deck floors, hammocks, &c., and the tender now attached to the "Formidable" will be retained for the training of the boys.

Mr. G. F. Bodley, A.R.A., is the Prime Warden of the Fishmongers' Company.

Mr. David Marshall, a well-known Scottish antiquary, died last week at Kinross.

The New Board Schools at Cradley being erected in Colley Lane by Mr. H. Dorse, contractor, of Cradley Heath, Staffs, are nearly completed. They are now entirely roofed, and most of the glass has been put in.

In reference to the New Workhouse Infirmary, Sunderland, described on p. 326 of our issue for December 25th, we may mention that Messrs. E. H. Shorland & Brother's central patent Manchester stoves with descending smoke-flues are in use in all the various infirmary wards.

A Monument to M. Armand Rousseau, formerly Governor-General of Indo-China, is about to be erected at Brest. The work will be executed by the sculptor Denys Puech in collaboration with the architect Vandremer. The statue is in bronze, mounted on a quadrangular pedestal of granite.

The Victoria College at Alexandria, the building of which by a firm of English contractors has just been completed, has cost £3,000. It covers an area of 600 sq. metres, and has a frontage of 30 metres, with six large windows of Gothic design. The foundation stone of the building was laid in May last by Lord Cromer.

The Roman Catholic Cathedral, it is authoritatively stated, will not be opened in the present year. Although the building seems to the outside spectator to be approaching completion, it is far from finished, and the work in the interior is so extensive that the time for its completion is as yet merely a matter for conjecture. It is probable that before the building is completed and formally opened services will be conducted in one portion of it. Even this, however, will not take place by the time of the Coronation.

The King's Sanatorium.—Three premiums of £500, £200 and £100 respectively are offered for the best essays and plans of the sanatorium for tuberculosis to be erected in England with the £200,000 placed at the King's disposal by Sir E. Cassel. These essays and plans may be by a medical man alone, or in collaboration with an architect. They are to be sent in by April 15th to the Advisory Committee, addressed to Dr. P. Horton-Smith, 15, Upper Brook Street, W. Further particulars are given in the current issue of the "British Medical Journal."

Dr. Baurath von Schich, the well-known Palestine explorer and one of the best authorities on the topography of ancient Jerusalem, died in that city recently at the age of eighty years. Dr. Schich was one of the first Europeans who came to settle in Jerusalem, where he lived nearly fifty-five years, having left Wurtemberg, his native country, in 1846. First working as an architect and afterwards occupying himself in study and researches, he became thoroughly acquainted with the history of the country, especially with "Underground" Jerusalem. The deceased was a regular contributor to the quarterly statement of the Palestine Exploration Fund, and has made a unique and beautiful model of the Great Temple of Solomon during different periods—a model which is familiar to most of the tourists who have visited the Holy City during the last fifteen years.

Builders' Notes.

Alderman John Worrall, builder, of Congleton, died recently.

Mr. Thomas Turner, builder, of St. Margaret's, Norwich, died recently in his seventy-first year.

Mr. John Ham, builder, of Plymouth, died recently at the age of seventy-one years.

British Institute of Certified Carpenters.—The report of the session ending December last states that the membership has increased, fifteen having been added last year, bringing the total now upon the books to 135, not including hon. members. After several exhaustive meetings, the rules have been revised—by which associate members are admitted to the Council. An entrance fee has been adopted, together with increased subscription for the associate members.

Change of Address. — Messrs. Kirkpatrick Brothers have removed to the Manchester Granite Works, Trafford Park, Manchester, where they have secured two acres of ground immediately adjoining the ship canal. Their new works contain a full complement of the most modern machinery, all driven by electricity, for sawing, turning and polishing granite or other stone, including pneumatic tools for ornamental scroll and carved work. A large stock of British and foreign granites of every variety is held, and orders for any description of work will be executed with the utmost despatch. The position of the new works enables granite to be imported at a minimum of cost. Messrs. Kirkpatrick Brothers have been appointed sole agents for the Closeburn red freestone which has been largely used for important buildings in the North, and they hold a large stock of the stone. The depôt of the Bath Stone Firms, Ltd., also, is on their ground. Bath and Portland stones may always be obtained from stock.

Trade and Craft.

Door and Window Fasteners.

To adapt an old saying, one might observe that "of the making of window-fasteners there is no end"; which goes to prove that the old-fashioned article does not thoroughly satisfy requirements. "Podmore's Storm Fastener" (manufactured by Messrs. Colledge & Bridgen, of Wolverhampton) consists of a strong square bolt fixed to a base plate on the back sash and having at its opposite end a thumb-screw which passes into a countersunk hole in the base plate on the front sash. One turn of the screw fastens the bolt securely, lifts up the back sash, and draws the windows tightly together, so preventing draughts or rattling. The fasteners are supplied in black iron (with brass screw) at 10s. per dozen, or in brass at 14s. 6d. per dozen.

Anaglypta.

The Anaglypta Co. of Darwen have issued a new catalogue of their productions, which now, by the way, include the Salamander fireproof decorations. In addition to designs, actual specimens of material are bound up in the volume, thus enhancing its value as a book of reference. The designs are printed from photographs in a manner that does credit to the printers. A number of useful hints are given with regard to fixing, painted walls, damp walls, &c., and the application of the material to door-panel decoration. We have also received a separate book containing *inter alia* a representation of the beautiful peacock frieze and filling by Mr. G. C. Haité, with other designs by the same artist, and by others; and if any decorator desires to use the best material, and use it to the best advantage, he cannot do better than obtain these catalogues of the Anaglypta Co.

Sanitary Goods.

Considering how cast-iron sanitary pipes and fittings are being so increasingly employed, architects and builders should consult the new catalogue issued by Mr. John Jones, of Carlyle Works, Chelsea, S.W. The improved intercepting chamber illustrated therein is covered at the ground-level by a patent ventilating cover and frame which allow condensed moisture and any liquid that may percolate through the vent-holes to be carried away by a draining pipe and discharged into dry rubbish. The cover of the inspection chamber is so constructed that any packing that may be used cannot become rotted and so allow foul gases to escape: a wrought-iron brindle and heavy gun-metal screw afford a secure and strong fastening. The inspection-eye cover is double-sealed, and the clearing arm to the sewer is provided with a patent lever stopper which can be readily opened. Joints would be made with metallic lead, and there would thus be no risk of leakage. The castings have a specially-smooth inside surface, and are glass enamelled or coated with Dr. Angus Smith's solution. The special features of the improved cast-iron gulley shown in the catalogue are that the outlet at the bottom can be arranged to suit the exact fall of the drain, and that the middle and top pieces are made in various lengths for forming the connection between the trap and the ground-level; moreover, the middle pieces have one, two or three inlet sockets, and, being circular, can be turned round without disturbing the trap. Of the various kinds of manhole covers made by Mr. Jones are some with the tops recessed to receive tiles, mosaic, wood blocks or any other flooring to harmonize with the surroundings—a most happy provision. Several varieties of stable gulleys are shown in the catalogue; the "Drayton" retains sufficient water to ensure proper trapping and cleansing, but avoids a large body of stagnant water; while a particularly neat gulley-grating is illustrated on p. 34, being circular (either arched or flat) and fitting in a square frame. Mr. Jones is, in addition, a manufacturer of baths, lavatories, urinals, sinks, water-closets and other sanitary fittings; and he is also the patentee of the "Unfreezable" cistern overflow valve and of several drain-testing appliances.

TENDERS.

Information from accredited sources should be sent to "The Editor." Results of Tenders cannot be accepted unless they contain the name of the Architect or Surveyor for the work.

CHERRYHINTON (near CAMBRIDGE).—For sewerage works for the Chesterton Rural District Council. Messrs. Waters & Worrall, engineers, 2 Sidney Street, Cambridge. Messrs. Beesley, Son, & Nichols, consulting engineers, Westminster, S.W.:—

Masters and Men.

The Coventry Building Trade.—Notices in the Coventry building trade for any variation in the scale of pay have to be served by the end of any year. In 1900 the masters' notices for reduction, &c., went in too late, as the Board of Trade arbitrator ruled. The employers have again given notice of reductions of ¾d. per hour in skilled workmen's wages and ½d. on unskilled labour; the men have replied with a demand for an increase of wages.

The Bristol Building Trade.—The Bristol Master-Builders' Association have given six months' notice to reduce the wages of all employees by 1d. per hour. Slackness of trade and the overflow of the labour market are assigned as the reasons, there being more men out of work than for several years past. The war has seriously affected trade, and the enhanced cost of labour and material has checked building enterprise. At present skilled workmen are receiving 9d. per hour, averaging £2 per week, and the proposed reduction represents 4s. weekly. The builders' labourers, earning about 27s., will suffer the most seriously by the threatened reduction, which is viewed with dismay.

Bradford Building Trade Dispute.—Negotiations between the representatives of the labourers employed in the Bradford building trade and the Bradford and District Master Builders' Association have resulted in the settlement, so far as the labourers are concerned, of the dispute which has been in progress since the 1st of May. The cause of the dispute was the refusal of the masters to grant an advance of 1d. per hour in the wages paid, and the men left work at the same time as the masons and joiners, who were and are still resisting a reduction of ½d. per hour and certain alterations in the rules regulating employment. Recently the secretary of the Labourers' Union wrote to the Master-Builders' Association stating that the men desired to withdraw their demand for an increase of wages, and asking that they might be reinstated as early as possible, without prejudice or malice. A conference followed, at which the men expressed their willingness to come to terms on the basis of the arrangement which prevailed in 1894. This offer was accepted, and the masters decided to circularise the federated employers, stating that "although they feel that it will be difficult to find employment for all the men at once, it is hoped they will replace the men as early as ever possible without prejudice." The terms of settlement provide that the wages shall be 6d. per hour. During the course of the dispute the men have been in receipt of 10s. a week as strike pay, but the funds are now nearly exhausted. The number of men ready to start work again is about 120. As regards the masons and joiners the settlement of the dispute seems as far off as ever. In both cases the men are receiving an out-of-work allowance of £1 per week; and as they have wealthy unions behind them, it would seem that they will be able, unless the improbable contingency of a general strike should arise, to continue the struggle indefinitely.

New Companies.

Cotterell Brothers, Ltd.

Registered to acquire the business of paperhangings merchants carried on by F. F. Cotterell, H. F. Cotterell and T. S. Cotterell at Bristol, Bath, and London, as Cotterell Brothers, and the business of wallpaper manufacturers carried on by G. F. Turner and E. A. S. Cotterell, or one of them, at Chelsea as Scott, Cuthbertson & Co., and to carry on the business of manufacturers of and dealers in wallpapers and other decorations, paints, varnishes, brushes, artists' and decorators' materials, &c. Capital £85,000 in 2,205 preferred "A" and 3,105 preferred "B" shares of £10 each and 6,380 ordinary shares of £5 each. The first directors are F. F. Cotterell, H. F. Cotterell, T. S. Cotterell, A. P. I. Cotterell and E. A. S. Cotterell. Registered office: 10, Clare Street, Bristol.

S. & E. Collier, Ltd.

Registered to acquire the business of brick, tile, pipe and pottery manufacturers carried on by E. P. Collier, S. G. Collier and D. F. Cooksey at Grovelands, Reading, as S. & E. Collier, and to carry on and develop the said business and the general business of manufacturers of and dealers in clay goods, &c. Capital £70,000 in £1 shares (54,000 preference). The first directors are E. P. Collier, S. G. Collier and D. F. Cooksey. Qualification £50. Remuneration £2,000 per annum, divisible.

COMING EVENTS.

Wednesday, January 8.

Society of Arts.—Sir Henry Trueman Wood on "Photography and its Applications"—II., 5 p.m.

Geological Society of London.—Meeting at 8 p.m.

Northern Architectural Association.—Students' Evening.

Society of Biblical Archæology.—Annual Meeting at 8 p.m.

Thursday, January 9.

Manchester Society of Architects.—Spécial General Meeting to elect a Fellow and an Associate. Mr. J. D. Crace on "Relation of Colour to Architecture," 6.45 p.m.

Society of Antiquaries of London.—Meeting at 8.30 p.m. Ballot for Election of Fellows.

Institution of Electrical Engineers.—Discussion of the Technical Reports of the Institution Visit to Germany, 1901, by the Committees on Traction, Light and Power, Manufacturing, and Telegraphs and Telephones, 8 p.m.

Sheffield Society of Architects and Surveyors.—Mr. W. Watts, F.G.S., on "Concrete and its Use."

Royal Institution.—Prof. J. A. Fleming on "Waves and Ripples in Water, Air and Æther"—VI., 3 p.m.

Friday, January 10.

Architectural Association (Discussion Section).—Mr. P. W. Mulready on "The Work and Influence of Augustus Welby Pugin," 7.30 p.m

Glasgow Technical College Architectural Craftsmen's Society.—Mr. A. B. M'Donald, M.I.C.E., on the 'Highlands of Central Europe," 8 p.m.

Birmingham Architectural Association.—Mr. John Ward on "Pictures from Penzance and the Land's End."

Monday, January 13.

Surveyors' Institution.—Mr. John H. Hanson, F.S.I., on "Rivers' Pollution : Purification of Trade Waters from a Mill Occupier's Point of View," 8 p.m.

Society of Arts (Cantor Lecture)—Mr. Samuel Rideal, D.Sc., F.I.C., on "The Sterilization of Water"—I., 8 p.m.

Royal Geographical Society.—Dr. Logan Jack on "A Journey from Shanghai to Bhamo," 8.30 p.m.

Royal Academy.—Prof. V. C. Prinsep, R.A., on Painting"—I., 4 p.m.

Bristol Society of Architects.—Mr. F. Bligh Bond, F.R.I.B.A., on "Rood Screens, English and Continental," 8 p.m.

Tuesday, January 14.

Royal Institution.—Dr. Allan Macfadyen on "The Cell: Its Means of Offence and Defence. Immunity"—I , 3 p.m.

Institution of Civil Engineers.—Mr. Henry Bridges Molesworth, M.I.C.E., on "American Workshop Methods in Steel Construction," 8 p.m.

Wednesday, January 15.

Surveyors' Institution.—Students' Preliminary Examination (First Day).

Northern Architectural Association.—Mr. James Bruce on "Recent Data concerning Concrete Beams and Concrete Floors," 7.30 p.m.

Society of Arts.—Mr. Frank J. Gray on "Elliptographs," 8 p m.

Chemical Society.—Meeting at 5.30 p.m.

British Archæological Association.—Meeting at 8 p.m.

Institute of Sanitary Engineers.—Presidential Address by Dr. J. C. Thresh, M.D., D.Sc., 7 p.m.

Thursday, January 16.

Surveyors' Institution.—Students' Preliminary Examination (Second Day).

Leeds and Yorkshire Architectural Society.—Dr. N. Bodington on "Schliemann's Troy," 6.30 p.m.

Royal Academy.—Prof. V. C. Prinsep, R.A., on Painting"—II., 4 p.m.

Society of Antiquaries of London.—Meeting at 8.30 p.m.

Royal Institution.—Dr. A. S. Murray on "Recent Excavations at Delphi and in the Greek Islands"—I., 3 p.m.

Society of Arts.—Mr. Francis Henry Skrine on "Bengal: The Land and its People," 4.30 p.m.

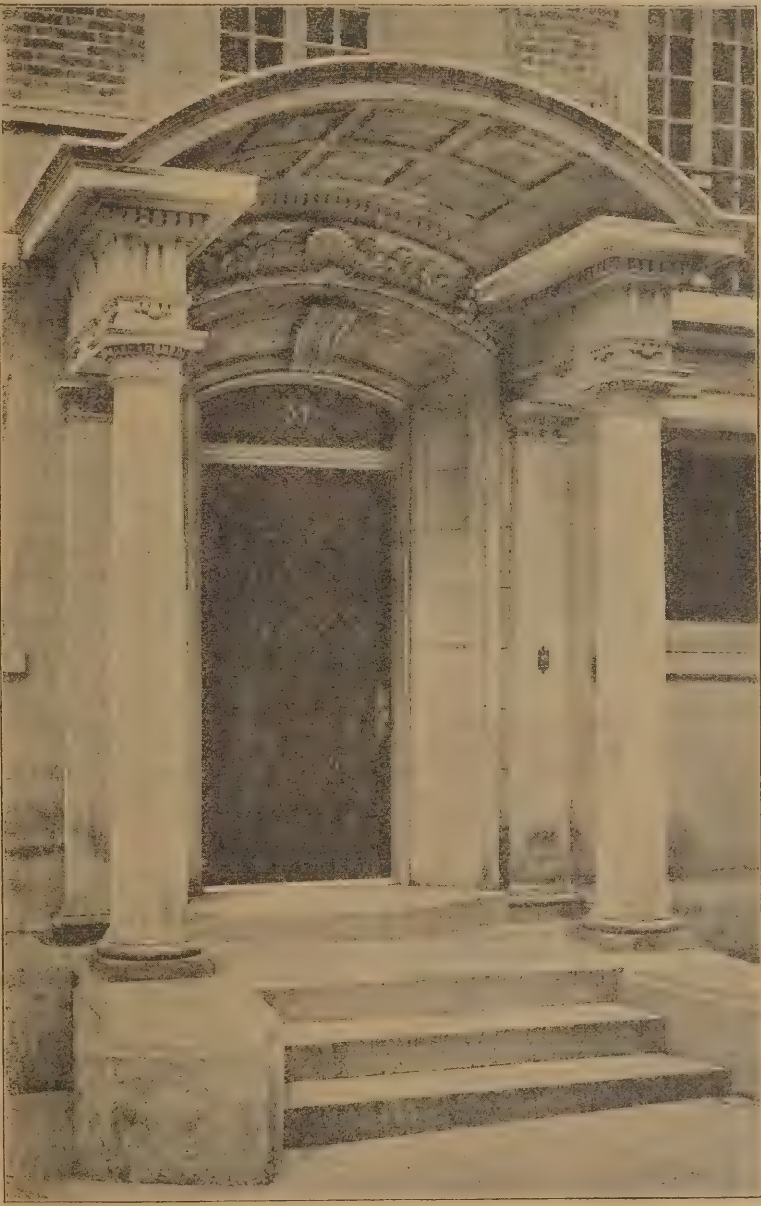
An Architectural Causerie.

Another Case of Overloading. REFERENCE has already been made in these columns to the dangerous practice of piling goods on floors and landings which were never intended to sustain such weights, and we specially mentioned printing houses, where the heavy "formes" are packed together in hundreds without any thought of the strength of the supports. Last week a case of overloading resulted in two workmen being severely injured in London. It appears that a house at the corner of Bridewell Place and Tudor Street was being pulled down, and that owing to the heap of bricks placed on the first floor after the demolition of the upper portion of the house, an iron girder on this floor broke and a collapse occurred; a foreman and a labourer being buried in the debris. This shows how necessary it is to observe the fact that floors are only intended to support certain weights.

"Hearts of Oak" Competition. IT is worthy of note that in the "conditions" issued to competitors for the Hearts of Oak Benefit Society's new head-offices to be erected in Euston Road, London, the suggestion was made to avoid "fussy" detail as far as possible and also to avoid unnecessary finishing of the drawings; "so long as the design is as clear and as simple as possible, this is all the assessor wishes." Mr. Sidney R. J. Smith, F.R.I.B.A., was the assessor, and he is to be congratulated on the manner in which he has carried out his duties. The twenty-two sets of designs submitted are exhibited at the Society's present head-offices at 17, Charlotte Street, Fitzroy Square, W., and on the whole they are of very fair merit. Undoubtedly the best plan is that which has been awarded the first premium of £100 (it is numbered 17, but the authors' names are not yet made public). This plan is particularly straightforward, and the various offices are arranged in a manner which affords convenience to the working staff and to the depositors who attend in such numbers. The general office (78ft. by 38ft.) is placed at the rear of the site (which is next westwards to the Women's Hospital), the object being to get light from three sides. The building is set back from the old line, and the central entrance in Euston Road leads to a vestibule having an enquiry office at one side and a physician's room at the other. Beyond is the main entrance hall with doors opening into the general office, around which the various rooms for the staff are arranged, while a postal room is provided at the back end. On the first floor is the delegates' hall (to seat 310), extending up two floors, and covered by a domed roof. The rest of the first floor, and the second and third floors, are occupied by numerous rooms for the staff, and living quarters. In the basement are a letter-room 38ft. by 35ft., several strong-rooms, typewriters' room (58ft. by 14ft.), an order-room (43ft. and 14ft.) and other accommodation. The public space in the general office is lighted by a domed skylight in the internal open area from the first floor upwards, which also lights the staircase, halls and corridors. The secretarial department is mostly on the mezzanine floor over the entrance. The architects' estimate (893,479 cub. ft. at 11d., and additions) amounts to £48,601, which is in excess of the sum stated in the conditions (£45,000), but the cost would be £3,331 less if the buildings were kept to the present line and not taken back further, though this would mean a loss of light. Heating is by low-pressure hot water; ventilation mostly on the "Natural" system; the external elevations to Euston Road and Grafton Place to be in grey Aberdeen granite to the basement floors and Portland or Derbyshire gritstone for the rest of the building. The design which has been awarded the second premium of £75 is numbered 3. Its plan (which shows the general office with a circular counter) is nothing like so good as the other, and the elevation to Euston Road, "Italian Renaissance classically treated," is most distressing. The architects' estimate is £46,048. The design numbered 22, which is awarded the third premium of £50, is better. The authors think it would be found impossible to adequately light the general office from the sides only, so they have provided a large lantern over the centre, supplemented by windows at the sides. The estimate is put at £44,966. Of the remaining nineteen sets of designs, those numbered 5, 20, 2 and 12 deserve special mention: they all exhibit a careful simple treatment; but the rest do not call for any remarks. In all cases the competitors' observations are hung with their designs, a most desirable, though often neglected, requisition.



ENTRANCE PORCH, NO. 34, EAST 50TH STREET, NEW YORK.

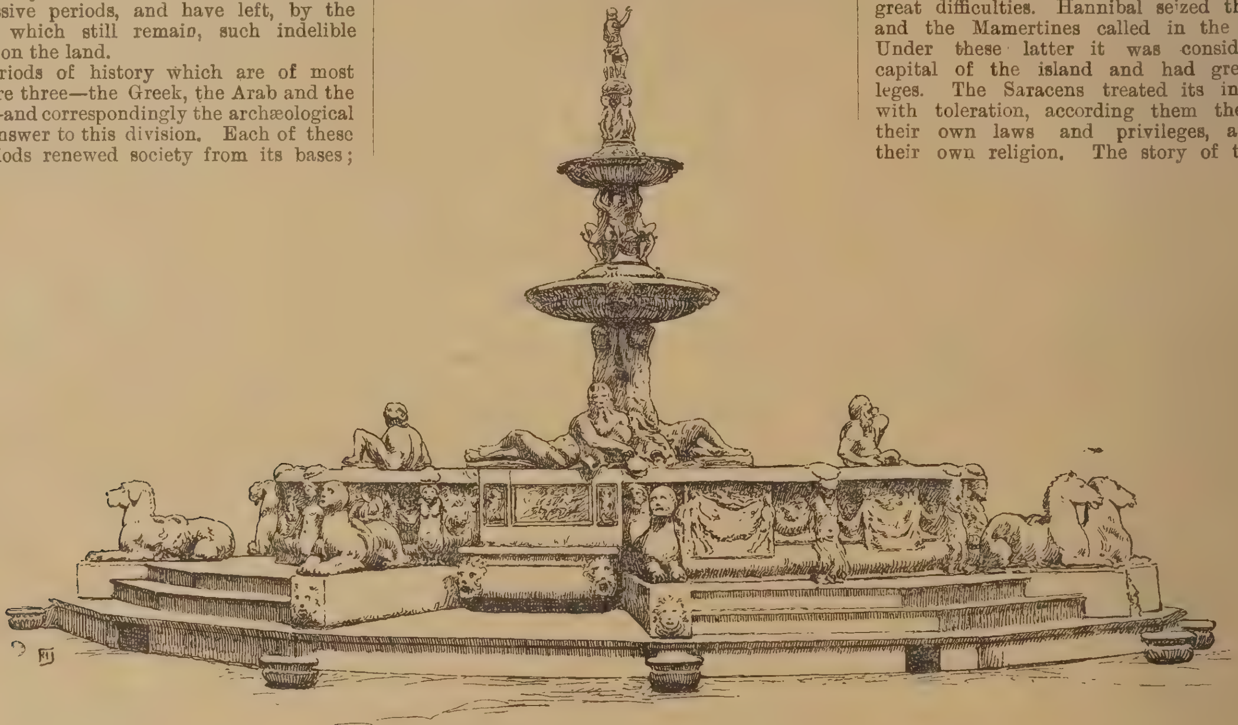
Piccadilly Widening. THE widening of Piccadilly is proceeding, and a strip will be taken off the Green Park varying from 11ft. to 35ft. in width. The average addition to the width of the road will be about 18ft. The alterations will cost £13,000, and will take between two and three months to complete. A concrete foundation for the iron railings is to be laid first, and then the outer path, which is to be of York paving, will be proceeded with. The present alterations constitute about one-third of the original scheme of widening, but whether they will prove of any material benefit remains to be seen. It is in the portion of Piccadilly from the Circus to St. James's Street that the congestion is so inconvenient; yet nothing is attempted to improve matters here.

SICILY AND ITS ARCHITECTURAL MONUMENTS.—I.

By F. HAMILTON JACKSON, R.B.A.

THE island of Sicily, by virtue of its position between Europe and Africa, has been liable to many vicissitudes, and has suffered many things at the hands of different masters who have left marks of their presence both upon the land itself and upon the people who inhabit it. Greek, Roman, Arab, Norman, Spaniard and Frenchman have all ruled there at one time or another; but the primitive stock, the Siculan, has modified and absorbed the various elements in the majority of cases, and the Sicilian character is still not very different from what it was many centuries ago. The island is triangular, one side facing the Ionian sea, one facing Africa, and one looking across the Tyrrhenian sea towards Italy, and these directions indicate the various influences which so profoundly modified the conditions of life at successive periods, and have left, by the buildings which still remain, such indelible marks upon the land.

The periods of history which are of most interest are three—the Greek, the Arab and the Norman—and correspondingly the archæological remains answer to this division. Each of these three periods renewed society from its bases; new laws were introduced, new customs, new religions and tongues with the admixture of fresh blood; in each such a change was made as if the past had never existed. The first was the Greco-Siculan, in which the island appeared as a Greek nation with Syracuse as head and representative, though the various communities, which were continually warring with each other, were some of them Greek colonies, some Greco-Siculan, and some Siculan entirely or with admixture of other peoples. This period made the island known to the world, and has left behind it considerable remains, many of which were a good deal altered in Roman times. Next came the Arab period, when the Byzantine rule had become weak and ancient civilization decadent. The new dominator brought his own laws and religion, the acceptance of which at least saved the Sicilians from the corrupt and thievish government of Constantinople. Palermo now became the capital of the island, which was divided into three great compartments called "Valli"; and by its beautiful buildings, by its immense population interested in science, literature, arts and industry, equalled the former reputation of Syracuse. The remains of their productions are few, but it was from their civilization that the Normans reaped such advantage and developed the magnificence which was so striking to their contemporaries, the remains of which are so admirable and the goal of so many pilgrimages. Under their rule the fusion of the various elements, Latins and Greeks, the barbarian tribes which had become Italianized on the peninsula, Lombards and Normans, Byzantines and Arabs, prepared the way for the Italianizing of the island. The French domination was but short and left scarcely a trace, but the Aragonese and Castilian rule introduced a Spanish influence which is very perceptible in the buildings of the later Gothic and earlier Renaissance periods—after which there is little or nothing worthy of note in Sicilian art.



FOUNTAIN OF ORIONE, MESSINA, BY MONTORSOLI. DRAWN BY F. HAMILTON JACKSON, R.B.A.

The two principal ways of reaching Sicily are by boat to Palermo from Naples, and by train to Reggio, from which a steam ferryboat crosses to Messina, conveying the mail van and trucks as well as passengers. A convenient plan to adopt in visiting the interesting places in the island is—starting from Messina, to proceed thence to Taormina, and, passing round the back of Etna, to visit the picturesque old town of Randazzo, a type of the inland mediæval towns; then continuing through Catania to Syracuse, and returning on one's steps as far as Bicocca, going through the centre of the island to Girgenti. Thence across to Palermo is not a very long journey, and several excursions may be made from that place; while Cefalù may be visited on the return journey to Messina. In this manner most of the celebrated antiquities, both Greek and Roman, may be seen, as well as those of the Norman Saracenic period, and at Cefalù may also be seen what is said to be the only piece of prehistoric architecture in the island, most probably erected by the Siculi. It is for its antiquities that Sicily is visited, though the scenery is also very fine; for the later Renaissance work has all the vices of the baroque, while the modern buildings are most of them very inferior; though at Palmero an enormous theatre has been erected which quite dwarfs the cathedral and the royal palace in a distant view of the town, being far the most conspicuous object on the skyline.

The harbour of Messina stretches around a curve the chord of which is about 3 kilometres, the more distant towers of the town rising above an almost continuous line of similar buildings which surround the port in what some consider a magnificent and others a rather dull fashion. The town is built on the sides and at the foot of a natural amphitheatre of hills, in a situation which is really fine, and should have excited the imagination of the builders or architects to accomplish, or at least attempt, greater things. It is from this curve, completed by the mole which terminates the port, that its ancient name of "Zancle," the sickle, was taken. This harbour is one of the best in the world, and is the busiest in Italy for steamboat traffic. The citadel, a work of the seventeenth century, from which the bombardment of 1848 took place (which gained for Ferdinand II., King of Naples, the epithet of King Bomba), lies across the harbour from the town, near the pier railway station. There are no remains of the antique period, although the city is of very ancient date, having been founded in 732 B.C., according to Greek tradition, on the site of a Siculan town. The name "Zancle" is, however believed to be Siculan, so that it is probable that the city was not destroyed, but only conquered, as happened in many other cases. The name of Messina, or Messana, was given it about the beginning of the fifth century B.C. by emigrants from Messina in the Peloponnesus, who came there while Anaxilas of Rhegium controlled the city. It was the cause of the first Punic War through the action of the Mamertines, a mercenary legion of Agathocles, cast out of Syracuse because of their turbulence, who came as friends to Messina, and being received in a friendly way treacherously assailed the citizens and, terrorizing them, gave a new name to the city, that of Mamerte. Their turbulent and aggressive spirit landed them in great difficulties. Hannibal seized the castle, and the Mamertines called in the Romans. Under these latter it was considered the capital of the island and had great privileges. The Saracens treated its inhabitants with toleration, according them the use of their own laws and privileges, and even their own religion. The story of the three Messinese who came to Roger Hauteville (whose first raid took place in 1060) to ask him to undertake the conquest of Sicily and liberate them from the infidel yoke can hardly be true, since their surnames are given, inasmuch as surnames were first used by the Venetians and at a later period than the eleventh century. Richard Cœur de Lion in 1189 wintered here with Philip Augustus, on which occasion there was fighting between the Messenians and Richard's troops, for which King Tancred rewarded Messina by conceding immunities and privileges which made it almost a free city. These were further increased a few years later under Henry the Sixth, who made it his favourite dwelling and base of operations, and it was here that he died in 1197. In the war of the Sicilian Vespers it was besieged for two months by Charles of Anjou, whose fleet was finally defeated by Roger de Lauria, the Spanish admiral, with so much effect that twenty-nine ships were captured and eighty burnt under the eyes of Charles, who "gnawed his fingers with rage" at the sight. In 1678, after internecine feuds and a period of French domination, the Viceroy Francesco Bonavides took away all the privileges of the town, picturesquely driving a plough over the site of the destroyed senatorial palace and sowing it with salt, while he left the doors of the archives of the cathedral open (from which he had removed all the precious documents recording the privileges accorded to Messina from the times of the Eastern Empire, and from Normans, Suabians and Aragonese).

The cathedral was commenced by King Roger on the site of another which had been used as a stable in Saracen times. It was consecrated on October 11th, 1197, and is the largest Arabo-Sicilian building which dates from those times. The nave has twenty-six antique granite columns, which are said to have come from a temple of Neptune near the Faro. The bases are made up with plaster, and the gilded caps are some of them of the antique Ravennese type, and some of the period of the foundation. The proportions are fine; but the later Renaissance work of the period when the dome was added (1682) has spoilt the effect. The pointed arches were then made round, with other alterations. The transepts are 145ft. wide and the nave is 305ft. long; this terminates in a semicircular apse, and the mosaics of the semi-dome date from the fourteenth century. They represent—in the centre Christ, with the Virgin and St. John, and Frederick the Second of Aragon (the donor) with his son Peter and Archbishop Guidotto; to the right St. John the Evangelist with King Lewis and the Duke of Athens; and to the left the Madonna with Queen Eleanor and Queen Elizabeth. They were much damaged by the earthquake of 1896, and it was found that the mastic which held the tesseræ had parted from the vault in many places, necessitating restoration, which is now proceeding. Beneath is the costly and tasteless altar, made up of precious Sicilian marbles. It was made in 1628 and cost 3,825,000 lire (!). Above it is a frame containing the celebrated Madonna della Lettera, a Byzantine painting of the fifth or sixth century (ascribed of course to St. Luke). Behind the altar in a little cupboard is the letter of the Virgin, reconstructed by Constantine Lascaris in the fifteenth century, the *soi-disant* original having been burnt in the conflagration of 1254, during the obsequies of Conrad the Fourth. The roof imitates the ancient roof; along the top is a row of sunk rose panels like those of the Capella Reale, Palermo. It is painted elaborately. The choir seats were carved by Giorgio Veneziano (1540), and are ornamented with panels in intarsia. There are some pretty Renaissance monuments and altars and a good font with marble inlays; the pulpit, by Calamech or Bonanno, is not so successful. In the choir are buried the Emperor Conrad the Fourth, Alphonso the Generous, and Queen Antonia, the widow of Frederick the Third of Aragon; and in the transept several archbishops, the tomb of one—Guidotto de 'Tabiatis, who restored the building after the fire of 1254—having been made by Gregory of Siena. In the south-west corner a piece of the original walling shows—alternate courses of white and black marble. The western façade has three pointed doors: that in the centre is the finest Gothic work in Sicily, as far as its ornamentation goes. The general effect is pinkish-white relieved with red, with a little inlay in bands which are bounded by courses of dark-green marble, panelled sinkings sometimes replacing the inlays. The Renaissance architects played strange tricks with the façade, adding monuments between the doors, huge scrolls rising to a cornice in the upper part and finishing with vases, other scrolls and funny Gothic crockets standing on their tails up the gable. The south aisle was restored in very modern-looking Gothic in 1865, when the towers and a great part of the apse were also reconstructed.

The fountain by Montorsoli in the piazza in front of the cathedral, who designed the side-altars also, represents Orione, the pretended constructor of the city by order of Zancleo, a mythical Siculan king. It was executed in 1547-51, and is upwards of 25ft. in height, a triumph in three storeys, overladen with allegorical figures of the Nile, the Ebro, Tiber and the brook Camara, near Messina. His other fountain on the Marina with a figure of Neptune is poorer in conception and execution, though much lauded. Not far away in the Via Primo Settembre is the narrow façade of the Norman church of La Cattolica. An inscription calls it "the Mother of the Greek Churches." It has pointed arches with zigzag mouldings and carving of a later character on the caps. A little further away in the Piazza dei Catalani is the oldest Norman church in Messina, the Santissima Annunziata dei Catalani. Half of the apse is still visible in the Via Garibaldi—the caps are pleasing, and beneath the arcade are inlays resembling those in the apse of the cathedral of Pisa. It is said that the site was once occupied by a temple of Neptune, and afterwards by a mosque. Antique columns are used in the interior. The effect of the openings in the façade is damaged by a finicking dog-tooth moulding. At the side is a fine doorway with a three-centred arch, now leading to the Albergo del Genio, which looks almost Spanish or Portuguese. Similar doors are not infrequent in the Sicilian towns, and many examples may be seen in Taormina. They date from the fourteenth century. Another Norman church, S. Maria Alemana, is now used as a storehouse. Most of the remaining churches and the palaces are the work of the sixteenth and later centuries, and are not interesting. The church of S. Francesco was an exception, as it dated from 1251, but it was burnt down in 1884. The Rocca Guelfonia at the top of the town is said by local historians to be the ancient acropolis. Here the castle of the Mamertines is thought to have been; but, however that may be, there is no doubt that when Roger of Hauteville became master he strengthened the fortifications then existing and fixed his dwelling-place there when visiting Messina. Frederick the Second had his palace down by the harbour on the site now occupied by the Dogana.

WEST DOOR OF CATHEDRAL, MESSINA. DRAWN BY F. HAMILTON JACKSON, R.B.A.

[ALL RIGHTS RESERVED.]

THE GEOMETRIC INTERPRETATION OF PHOTOGRAPHS AS APPLIED TO SURVEYING AND OTHER PURPOSES.*

By J. BRIDGES LEE, M.A.

FOR the purposes of this paper we may define a photograph as a light-printed picture on a plane surface, obtained with the aid of a good modern photographic lens. Any rules and principles applicable for the interpretation of a true photograph will be equally applicable to any accurate process-reproduction of pictures originally obtained by photography. Now the one great generalisation upon which the whole science of metrophotography mainly depends is the truth that all good photographs are mathematically-correct projections. The photographic projection is a true perspective, with the focal distance as distance line.

If the eye of an observer could examine any ordinary plane photograph through a small aperture at exactly the right distance in front of the picture along the correct axis of vision, then all points in the photographic picture would appear to occupy exactly the same relative positions as the corresponding objects would have appeared to occupy if observed by one eye placed at the station-point where the lens was placed when the original picture was taken.

For practical purposes we may consider that rays of light proceeding in perfectly straight lines from the object point have all passed on as straight lines through the station-point until they met the photographically sensitive surface inside the camera.

This is not quite what actually happens, because the apex of the cone of entering rays is rarely or never coincident with the apex of the cone of emergent rays. They are always separated by a greater or less distance along the principal axis of the lens; but if they are very close together (as in fact they generally are with the best modern lenses), and if the objects to be depicted are far away and the angle embraced by the picture of moderate amplitude, the maximum error which may result from treating the apex of the cone of emergent rays as the common station-point for images and also for objects will be infinitesimal.

Again, it is not of course literally true that all rays which reach the picture plane have actually travelled in straight lines from the object points. On the contrary we know that the lens has collected rays over a fairly considerable area, and refracted them, so that only a very small portion of the rays coming from the object points will succeed in travelling in approximately straight lines through the lens to the corresponding image points. But the resultant effect is as though the rays had all travelled in perfectly straight lines through a single point; in other words, the refracted rays are brought to a focus at the same points on the picture plane where the unrefracted rays meet it.

It is quite an easy matter to prove experimentally that a good photograph taken with a good modern lens is a true projection.

In a paper which the present author read before the Camera Club on December 7th, 1899, published in the Journal of the Camera Club for February and March, 1900, this subject was discussed at some length, and a simple experiment described for verifying the general proposition. Perhaps the best of all possible ways to prove that a photograph is a true mathematical projection is to observe that perfectly straight lines will always project on a photographic picture as straight lines or as points, never as curved lines, if the lens is good. It can also be ascertained by measurement that the direction and length of the images will always be exactly what they should be with reference to the direction and length of the object lines, and to the known laws of geometry and perspective.

It is quite necessary to get a clear mental grasp of the broad generalisation that all good photographs, large or small, are true perspectives. It is possible for photographs taken with a good lens to yield wrong impressions; to a casual observer they often do, especially what are called short focus, wide-angle pictures; but the mathematical projection is always right, and the pictures would look right if we could get our eyes to see them from the right points of view and to embrace so large angles.

Now, let us suppose it to be accepted and clearly understood that a photograph is an accurate perspective. It follows of course that all the laws of mathematical perspective apply to the interpretation of photographs.

Suppose, therefore, that we have the necessary data, we should be able to interpret photographic perspectives just as we should well-made perspective drawings. We must of course have the necessary data, and the subject should be suitable in order that the rules of perspective may be applied with advantage for the construction of ground plans and elevations direct from the pictures.

In a general way it may be said that most large human constructions in the shape of buildings, great engineering works, roads, canals, &c., could be fully measured and plotted in plan and elevation from photographic perspectives, as also could the outlines of lakes and bays or other natural level-surfaces.

There can be no doubt, however, that perspective, except as applied to simple geometrical forms and figures, is essentially a difficult subject to study, and a more difficult one to apply to practical use. People get puzzled and confused with a multiplicity of vanishing and measuring points, and construction lines often at very acute or obtuse angles, and excessive care and much time are necessarily required to produce really reliable results, so it may be feared that if we had to depend too largely or entirely upon regular perspective methods, such as are generally employed by architects and others, metrophotography would at best make only slow progress in popular favour. Fortunately we are not driven to depend on the inversion of the ordinary methods of perspective drawings for interpreting photographs. We can generally get along very well with a few simple rules of practice, which are based upon sufficiently simple theory.

Suppose, for example, that we fall back on the conception of a photographic picture as a collection of tiny dots or points, each one of which is on the picture end of a straight line which originally started from a corresponding object point and traversed the station-point on its way to the picture, where it terminated in the dot under consideration. It is then evident that if we can set up the picture again in its proper position with regard to the station, any straight line from the station-point to any point in the picture will be a true direction line from the station to the corresponding object point. It follows that the angle included between direction lines joining the station-point to any two image points appearing on the face of the picture will be the same as the angle between direction lines from the original lens station to corresponding points in the actual objects whose images appear in the picture. Similarly, projections of those rays or direction lines on any horizontal ground plan will correspond exactly with the directions of rays drawn on a plane table, when that most simple and popular instrument for surveying is used.

It is, however, altogether necessary, when working with photographs, to possess certain auxiliary information concerning them. A number of reliable reference data are necessary to be known before it is possible to set up a photograph in correct position for sighting and drawing rays towards it—if we decide to adopt this very simple method for obtaining directions and intersections on a plan—and it is equally necessary that these same data should be given or ascertained whenever we desire to interpret the photograph. For example, it is essential to be certain about (1) the plane of projection. This may be vertical or may be inclined at any angle to the horizon, provided we know the angle, but in a general way it is best to secure that the plane of projection shall be absolutely vertical. In this position of the plane of projection, all vertical lines will appear vertical, and the operation of plotting ground plans and elevations from photographs is most easily performed when the photographs are either truly vertical or truly horizontal projections. To secure a truly vertical position for the plane of projection the camera used needs to be correctly constructed, and must be fitted with accurate levelling arrangements.

Then (2) we must know the traces of the principal vertical and horizontal planes where these planes intersect the picture plane. These traces will need to be recorded either by hand or automatically, as hereafter described, and they must appear on the picture as straight lines intersecting at right angles. The principal vertical plane and principal horizontal plane intersect each other along the principal axis, which meets the picture plane at the point where the vertical and horizontal traces intersect.

That point (3) is the principal point. It is a point common to three co-ordinate planes intersecting at right angles to each other. It is the true geometrical centre of the picture, in the sense that if a circle of any radius be described on the face of the picture with that point as centre, all points in the circumference of any such circle will be at the same angular distance from the principal axis. The principal point is also the nearest point in the picture plane to the station-point, and the length of the straight line joining the principal point to the station-point is the focal length, or distance line.

If we imagine a sphere with the station-point as centre, and focal distance as radius, then the picture plane will be tangential to that sphere at the principal point, and it is evident that angular distances can be measured in any direction along the picture surface from the principal point by aid of a tangent scale to a circle of radius equal to the focal distance. The importance of being able to find the principal point with unerring certainty can scarcely be over-estimated. That point alone is the only true origin of the three co-ordinates, which are necessary for an accurate determination of the three space dimensions, which need to be ascertained if we wish to fix with accuracy the true position in space of any point whose image appears as a projection on the picture plane.

Most commonly the principal point is to be found at or somewhere near the middle of the picture, but it need not necessarily be there, and it may even be far away from the apparent middle region; but wherever the principal point may be it is always the true central point for reference, and the three rectangular co-ordinates already defined, which radiate from it, are the true co-ordinate axes, each one of which is common to two reference planes intersecting at right angles. The photographic picture, which is obtained in the camera, is a projection on a vertical plane from (4) a definite station which as regards the picture is a definite point on the principal axis at a distance from the principal point equal to the focal distance. The principal axis (5), as before explained, is an imaginary straight line coinciding with the intersection of the principal vertical and principal horizontal planes. It is perpendicular to the plane of the picture, and therefore the station, which is a point on this imaginary line, is a point standing out in front of the picture at a distance from the principal point equal to the focal distance. As regards the lens by whose aid the picture was taken, the station corresponds with the second nodal point, or the apex of the cone of emergent rays.

The station as regards the objects photographed was a definite point at the apex of the cone of incoming rays which penetrated the lens. For reasons before explained, this point may be regarded in most cases as coincident with the apex of the cone of rays radiating towards the picture.

Its position ought to be known or ascertained with care and accuracy by any of the ordinary well-known methods for determining the position of a station, and it is well to bestow a lot of careful attention upon the correct fixation of the station-points; but, all other methods apart, it is well to know that the station-points can be determined from photographs in the same way as other points.

To determine the position of a station on a ground plan it is sufficient to be sure of a few direction lines from the station to points whose positions are already known and favourably placed for this method of fixation, or station-points can be fixed by the intersection of rays from photographs taken at other stations.

Then it is evidently necessary to know or to find out by some means the (6) orientation of the view, which can be most conveniently ascertained if we know the orientation of the principal axis, which we already know is perpendicular to the picture plane at the principal point. For the rest it is highly convenient, and for some purposes necessary, to have a scale (7) by which to measure on the picture angles subtended at the station. Lastly, it is convenient to have notes on a picture immediately available for the specific identification of every photograph directly it is taken in hand. Such notes may be made to indicate (*a*) the station number, (*b*) serial number of picture, (*c*) index reference to point bisected by trace of principal vertical plane, (*d*) barometric pressure or altitude of station, (*e*) date, (*f*) hour, (*g*) magnetic variation, and so on.

---

* A paper read before the Civil and Mechanical Engineers' Society on December 5th, 1901.

Before proceeding to consider how the photographs may be most easily interpreted with the aid of the reference data, let us turn attention to a specimen photograph, which bears on its face most of the information necessary for its correct interpretation (*see* centre plates).

The picture plane here was truly vertical when the photograph was taken. It can be seen that all the lines which we know to be really vertical in the objects depicted are also vertical in the picture. If the picture plane had been inclined, either backwards or forwards, the lines which are here vertical would have been neither truly vertical nor parallel, but either convergent or divergent, as every experienced photographer will know.

This picture was taken with an instrument similar to one shown by the accompanying illustration.

The verticality of the picture plane is secured by the construction of the instrument, and with the aid of the levelling screws and levels with which the instrument is furnished.

The station-point for this picture, as it now appears on the screen, is inside that lantern lens, and if it were possible to look at this picture with the eye placed where that lens now is, all directions and all dimensions would appear true and natural as though the real things were being looked at from the spot where the lens stood when the picture was taken.

The horizontal line right across the picture marks the trace of the principal horizontal plane, which contains the principal point and the station-point and all other points near or far which are on the same level as the station. Conversely, points which appears either above or below that line cannot be at the same level as the station, but must be higher or lower, as the case may be (when speaking of the same level as this place, account is not taken of the rotundity of the earth).

The vertical line marks the trace of the principal vertical plane. This plane also contains the station and principal point, and every point in that plane has the same azimuth as the principal axis. The intersection of those two planes is the principal axis, and the point where the traces of those planes intersect is the principal point.

The eye, being supposed to be at the station-point, will be looking straight along the principal axis, which, if materialised, would appear to the eye only as a point, and at the same time the two principal planes, horizontal and vertical, will appear edgeways if materialised, so that the two straight lines only will be seen as projections on the picture plane of their own respective planes.

The scale at the top of the picture gives an automatic record of the compass-bearing. The vertical hair serves as index, and it marks on the compass scale the magnetic bearing of the principal axis. The scale which stretches right across the picture is a tangent scale whose primary and chief use is to show horizontal angles at a glance. It serves also for the direct reading of the altitudes of all points in the principal vertical plane, and for reading unreduced angles in any direction from the principal point, the angle shown being the apical angle subtended at the station-point. This tangent scale also affords very ready and certain means for quickly and easily finding the focal distance for any photograph on which it appears, whether the picture be natural size or enlarged or reduced.

The equivalent focal length, or distance line, can be found geometrically by constructing a right-angle triangle, with a measured length of the tangent scale for perpendicular, to face an angle denoted by the measured length.

The base of the triangle will then be the focal distance. Or a measured length on the scale multiplied by the numeral value for the cotangent of the angle corresponding to that length will give the focal distance. The memoranda which are seen on the top corners of the pictures were made on slips of celluloid with ink and inserted in the camera before exposure, so that they and all other records were impressed and developed at the same time exactly as the picture itself.

Here then we have most of the necessary and useful reference data recorded automatically as latent images on the undeveloped plate, so that they spring into evidence at the same time as the picture to which they belong.

Most persons who have worked at the subject of metrophotography during the latter half of the last century have been driven to design special instruments for getting their pictures, because they found the ordinary cameras obtainable from the dealers of little or no practical use for accurate metrophotographic work, and all workers who have designed instruments have realised the necessity for having some definite guides to assist them in finding the principal point and the traces of the principal horizontal and vertical planes; but even the best designed of those instruments had no better arrangements for finding those essentials than by inserting pointers or cutting notches in the margins of the frames against which the photographs were pressed at the time of exposure.

The lines were afterwards ruled by hand between the images of the points or notches, and no other reference memoranda of any kind were impressed upon the picture at the time of exposure. One result has been that the operator has always had to attend to many observations, and to make numerous notes when taking photographs; and the risks of going wrong in various ways then and afterwards in the office were necessarily considerable. It has been the privilege of the author to originate the idea of impressing automatically on the picture at the time of exposure the most important and essential data for interpretation, and to design workable

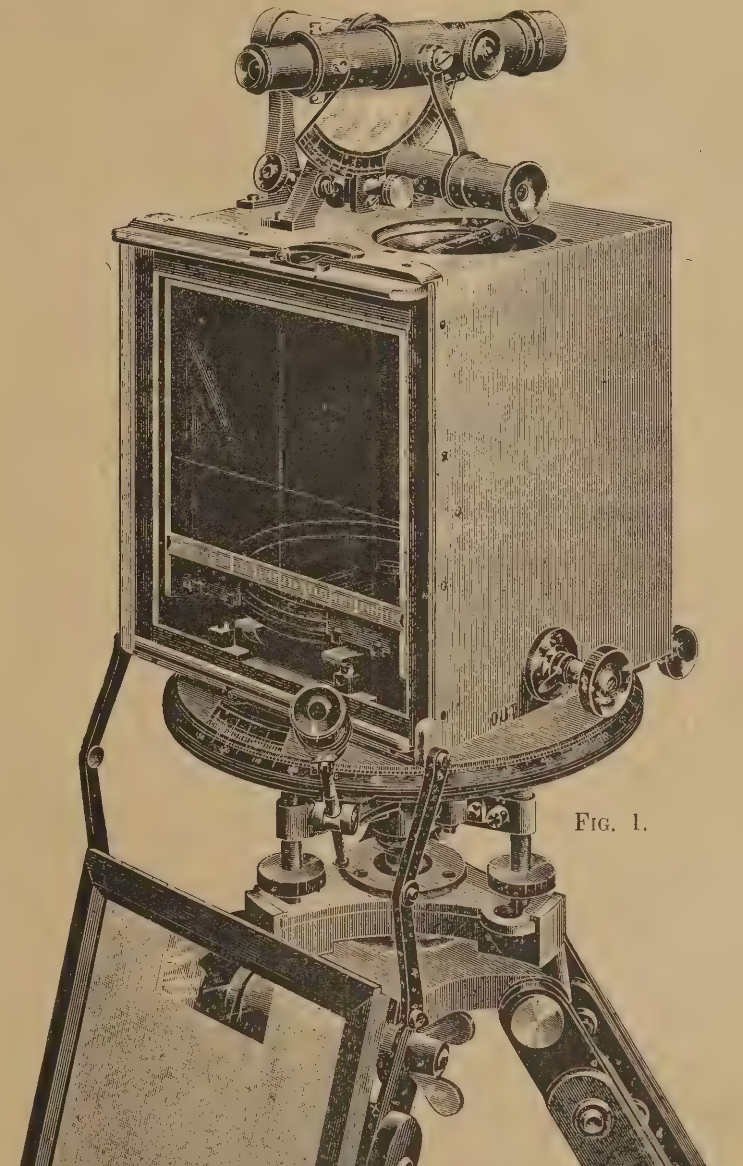

FIG. 1.

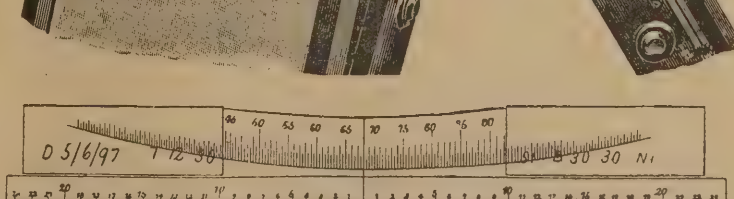

FIG. 2.

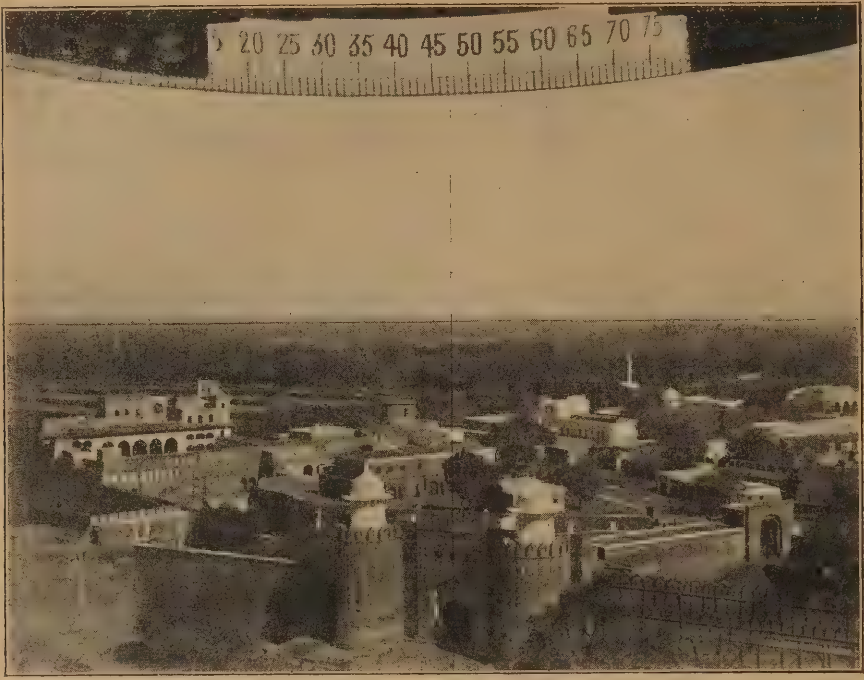
THE BRIDGES-LEE PHOTO-THEODOLITE.



PHOTOGRAPH OF FORT LAHORE, INDIA, TAKEN BY BRIDGES-LEE SURVEYING CAMERA.

mechanical means for carrying the general idea into effect in detail.

The earliest apparatus designed by the author for automatically registering the traces of the two principal intersecting planes and the compass bearing was made in 1894, and taken immediately to India. The accompanying photograph was one of many taken with that instrument. It is a view overlooking Fort Lahore. The tangent scale and other improvements have been added since.

One of the most important obstacles in the way of the rapid progress of practical metrophotography has been the great difficulty always experienced of getting efficient working tools.

The theory of metrophotography, which is really the theory of descriptive geometry and perspective applied to light-printed pictures, has been much studied and fairly well understood by experts, but the application of the theory to practical use has been difficult and puzzling, because of the multiplicity and complexity of the matters to be attended to and noted when using this method, and particularly at the time of taking the photograph. One chief aim which the author has had in view has been to simplify procedure both in the field and at home, and to secure additional certainty in results by substituting to a very large extent automatically-working mechanical arrangements for personal observation and record. It is possible to make a machine record data with extreme accuracy, and if the machine is in any respect out of adjustment the error will often be constant and can be detected and compensated, but human errors are more variable and cannot be so easily detected or compensated.

Time will not permit of any detailed discussion of instrumental appliances this evening; but before passing on to a brief review of some of the practical methods of working, it may be well to note that everyone who has devoted any serious attention to this subject has found that the ordinary photographic cameras of commerce are not adapted for accurate metrophotographic work, except under very limited conditions. The photographic camera has been fully developed as a toy by aid of which pictorial impressions are obtained with more or less apparent resemblance to the objects photographed, but for purpose of record a vast majority of the pictures which are taken have very little real value, and they cannot be interpreted for mensuration purposes, not because they are not true projections but because the key for the interpretation of those pictures cannot be found.

On the other hand, giving a suitable surveying camera, there is very little more trouble required to take good pictures which will be absolutely reliable records for all time so long as the pictures or reproductions from them continue to exist, and from which accurate surveys or exact detailed models can at any time be made of everything visible in the photograph.

The picture now on the screen (*see* centre plates S_1, No. 3, P_3) is a survey photograph overlooking Trafalgar Square, which presents a nearly full face view of the National Gallery as seen from a point on the roof of Drummond's Bank. The horizontal line in this, as in all other pictures to be shown, marks the trace of a truly horizontal plane containing the station point.

It is seen that it runs along the top horizontal ledge of the Gallery. The place where it cuts the monument is the same height as the top ledge of the National Gallery. If the view of the National Gallery were a perfectly full face one, then all horizontal lines on the full front view would be truly horizontal in the picture, and all vertical lines in this, as in the other pictures to be shown, are vertical, because the picture plane is always vertical. It follows, therefore, that all linear dimensions in a frontal view are exactly proportional to the linear dimensions of the object. The scale will vary with the distance of the object or with the focal length of the lens used, but all linear measurements will always be exactly proportional on object and image, and the ratio will be $\frac{d}{D}$, where d = focal distance and D = length of perpendicular from station-point to object plane.

The areas will, of course, be proportionate to d^2 and D^2. If we have a simple front view to deal with in any case all dimensions in the view can be easily read by aid of a pair of compasses and a scale, or by other elementary means.

A full front view of a plane surface is the very simplest possible kind of view to deal with. If the front view includes parallel surfaces at different depths or distances from the station, then, of course, the value of D varies, and the scales for different frontal planes will vary in inverse proportion to the value of D. In practice a very simple way to secure a good frontal view of a building is to set up the camera opposite the building, level it carefully, and then revolve the camera on its vertical axis until all horizontal lines in the building appear as truly horizontal lines on the ground-glass back; slight movements in rotation will cause perceptible changes in the directions of the images of the horizontal lines if those lines are near the top or bottom of the picture, and far away from the principal horizon line, which is the only line to remain always truly horizontal, whatever may be the azimuth of the principal axis.

It may be noted also that the area of the image is always largest with a frontal view. When dealing with buildings for measuring purposes it is best to use frontal views only as far as possible. It is not absolutely necessary that the lens should face the middle or any particular part of the building, but the plate should be parallel to the face of the building.

Next in point of simplicity to the image of a frontal plane surface is the image of a horizontal plane surface overlooked by the camera station: a lake, for example, or level ground like the interior of Trafalgar Square. The ground plan of a level area can often be plotted from a single photograph by ruling the requisite lines to divide up the area to be plotted into a number of horizontal squares in perspective, and then noting the particular squares in which particular points are to be found and placing them in their appropriate regular squares in a plan drawn on section paper. For this method of plotting it is necessary to know the principal point with exactitude, and also the two co-ordinate axes in the picture plane; and the station should be at sufficient angular elevation above the area to be dealt with, otherwise the perspective squares cannot be rightly placed or distinctly identified, and the plotting by this method will then become inaccurate. A much more general method of procedure is to plot ground plans by the method of intersections, and then to ascertain attitudes by observing the angular elevation as seen from the station point.

For plotting by intersection, views from two or more stations are necessary. It will be seen that this method is really a kind of plane tabling, and there is no reason why actual plane tabling should not be performed on magic-lantern projections in a room just as the same operations would ordinarily be performed on natural objects *in situ*.

There are, besides, very many instrumental and simple geometrical devices which may be used with advantage to assist in the correct interpretation and measurement of photographs; and in time, as the science and art of metrophotography continue to make progress in popular favour, other improvements also will no doubt be brought to light. But this is certain: that whatever future developments may bring forth, it will always be necessary to depend on exact knowledge of the position of the principal point and of the three principal co-ordinate axes. Orientation will always be important, and it will always be necessary to have indubitably accurate information from which the exact position of the station-point can be readily determined. Further, it will always be advantageous to have ready means immediately available for the measurement of angular distances from the principal point and azimuths and altitudes. All this information is invariably to be found on any photograph taken with any modern surveying camera, fitted as the camera has been fitted with which most of these pictures have been taken and which have been shown here to-night.

In conclusion it may be observed that good survey pictures are very accurate detailed records of measurable facts, such as no mere verbal descriptions can rival. A library of good survey pictures would occupy an excessively small space by comparison with ordinary books, and yield much more exact detailed information than any descriptions and drawings.

The operation of taking good survey photographs of large, and especially inaccessible, objects is incomparably the quickest and most economical way to gather full data for the mensuration of these objects.

Survey photographs can be obtained by any moderately skilled photographer, provided he is equipped with automatically-registering cameras, so that the master-minds of superintending architects, surveyors, engineers, and others, can work effectively in the office on materials collected from many places which they may not have been able personally to visit.

For municipal, antiquarian, architectural and land surveying records survey photographs will in time be regarded as indispensable.

The Kensington Memorial to Queen Victoria is to take the form of a clock-tower, to be placed in the centre of Kensington High Street, opposite St. Mary Abbott's Church.

Correspondence.

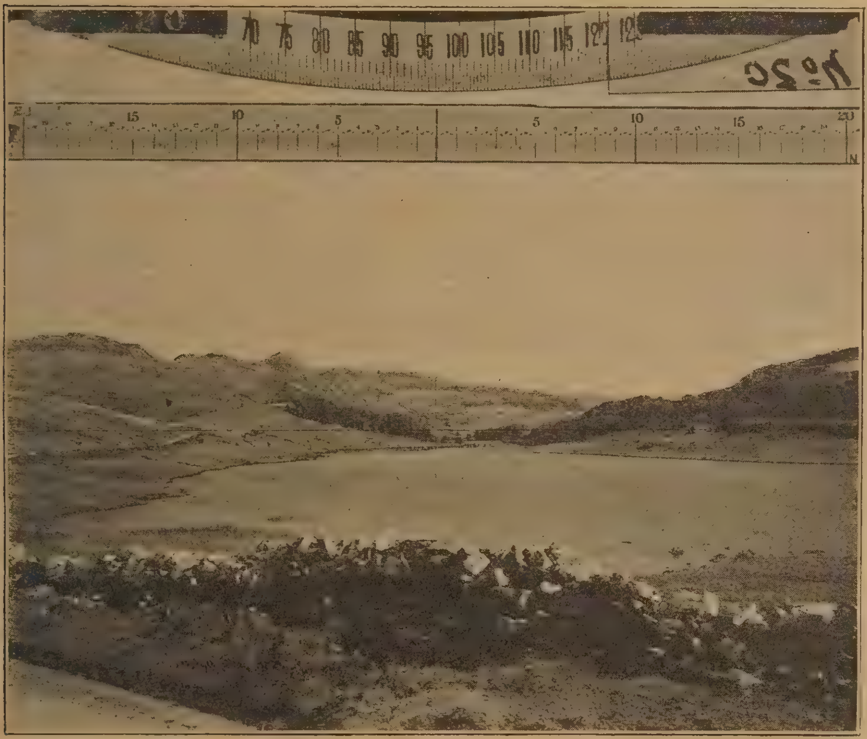
Army Works Reform.

To the Editor of THE BUILDERS' JOURNAL.

SIR,—In view of previous letters, the following hitherto unrecorded official matter will enable your readers to view the matter dispassionately. The sanitary condition of barracks impressed Mr. Campbell-Bannerman, when Secretary of State for War, with the necessity of appointing a specialist to counteract the ignorance of Royal Engineers in such matters. The Treasury, in reply to a letter requesting authority, said :—

Treasury Chambers,
Sir, 4th March, 1895.

In reply to Mr. De la Bère's letter of the 20th ultimo, I am directed by the Lord Commissioners of H.M. Treasury to acquaint you, for the information of Mr. Secretary Campbell-Bannerman, if it is the case that there is not a single Royal Engineer officer who thoroughly understands modern sanitary drainage, it appears to my Lords that they have no alternative but to sanction the continuance of Mr. Tyndale's services as sanitary engineer for a further period of five years, and they agree to his salary being raised from £400 to £500 per annum.



PHOTOGRAPH OF LAKE BALA, TAKEN BY THE BRIDGES-LEE PHOTO-THEODOLITE.

They suggest, however, it should be made a condition of the increase that Mr. Tyndale should instruct in sanitary science one or more young Engineer officers who might be attached to him as assistants, and learn his methods of dealing with large and difficult cases by personal observation.

I am, Sir,
Your obedient Servant,
(Signed) FRANCIS MOWATT,
The Financial Secretary, Secretary.
War Office.

A few months subsequent to this Lord Wolseley, commanding the Forces in Ireland, had occasion to report on the Royal Barracks, Dublin, scandal. He added the following post script dated June 5th, 1895 :—

This is, according to my views, a fair average specimen of the R.E. system of administration. I have long thought, of all parts of our system of military administration during peace that connected with the building and repair of barracks under the R.E. as designers and men of business most demands the attention of the military reformer . . . . I hope, however, it will be clearly understood that I am not finding fault with the officers employed, or those who directed their employment. My attack is not on them, but upon the system they do their best to administer. (Signed) WOLSELEY.

The belief that he is the man-of-all-work is instilled into the sapper's mind from youth upwards, until he believes in it as a species of false religion. It amounts to a description of fanaticism, *la folie des grandeurs*, which provides the corps with an exceptional proportion of eccentrics. These devotees are now impressing their reality on Lord Esher's Committee in shoals, but it is to be hoped that a clear-headed reformer like Mr. Brodrick will not rest satisfied with a report which will leave matters *in statu quo ante*, or, what amounts to the same, foisting military officers, at present incompetent, as permanent architects on the Barrack Department.

A similar Committee sat in 1862, which enquired into matters more minutely than the present one. It recommended that officers of Royal Engineers should seriously act as architects, and not rely on other officials whose duties should be distinct. They were given another chance, which has only resulted in a series of scandals, culminating in the present enquiry.

Before coming to a decision in the matter and evolving a new Works system, founded on the advice of Royal Engineers, Mr. Brodrick would do well to enquire into the very perfect one which exists in the German army, where the Barrack Department is civil and recruited from civil architects who have passed necessary Government examinations.—Yours truly,

ARCANA.

To the Editor of THE BUILDERS' JOURNAL.

SIR,—I am glad my former letter has called forth such excellent epistles as those of "Balbus" and "Thorough." Permit me to now add the following :—

Belfast.—New barracks have been erected at Holywood, about three miles from the city. They were only completed about a couple of years ago, yet in defiance of modern sanitation the sewage from them was openly discharged on to the foreshore of Belfast Lough without any attempt at purification. At low water this foreshore stretches for nearly half a mile, and the stench from the sewage in hot weather is described as intolerable. This affects not only the health of the troops quartered just opposite this outlet, but also that of the inhabitants of the town of Holywood itself, as well as the users of the rifle-range between a portion of the barracks and the shore.

Chatham.—Upwards of 300 men were housed in 1899 in the underground rooms of the Brompton Barracks, Chatham, which were ill-lit, ill-ventilated, and like cellars. This was a disgraceful state of things after the enormous votes of money for barrack-building during recent years.

Cyprus.—The housing of the troops in this island is lamentable. The offices, married-quarters and barrack-rooms are rough wooden huts, which are neither waterproof nor windproof, and present a disreputable appearance. The condition of the buildings is the more remarkable inasmuch as the native troops are lodged in comfortable stone buildings. A good deal of money has been spent in the last few years for engineer services at Cyprus, but the Royal Engineers were only represented at the station by a military foreman of works, who has been there about ten years and did just as he pleased.

Dover.—A short time ago some of the barracks were burnt down, owing to the proximity of the end of a purlin to a chimney flue—a piece of bad construction which every architect specifies against. When the town fire-brigade arrived it was found that the barrack hydrants would not fit the couplings of the town hose. One would have thought that even a Royal Engineer would have considered this. As far back as 1860 a civil architect, named Salvin, was employed by the War Office to design some barracks at Dover to harmonise with the adjacent ancient buildings ; he also carefully prepared a specification : yet when the documents were put into the hands of the Royal Engineers for execution they made the usual hash of the job, and the walls were so damp that the rooms were uninhabitable. It was found out afterwards that the amateur military architects did not understand the construction of rubble walls.

Dublin.—Everybody knows how £100,000 were absolutely squandered on the Royal Barracks, Dublin, between 1891 and 1893. The reconstruction of these buildings was undertaken because of the defective planning and bad drainage, for there were 127 cases of enteric fever in the Royal Barracks from January, 1879, to August, 1889. The Richmond Barracks were almost as notorious; and in the report made by Mr. Rogers Field, M.I.C.E., in 1889 he stated that forty-five cases of enteric had occurred between June, 1883, and June, 1889. The foundations of the buildings were found to be shallow and ragged, and there was no damp-proof course. The stone was so inferior that it crumbled away, and portions of the buildings had to be rebuilt. The subsoil water was not taken away, and among many sanitary defects two urinals were directly connected with the water main.—The reconstruction of the Portobello Barracks was to have cost £80,000, but this has been greatly exceeded. It was here that the Royal Engineers were responsible for bedding bricks in red lead—a novel way, certainly !—At the Marlborough Barracks our military friends were warned that English bricks would not stand the Irish climate, yet they insisted upon Essex bricks being used. They were dearer than the bricks made in Ireland, and there was the cost of carriage in addition. The Essex bricks did *not* withstand the Irish climate, and soon began to decay. In a short time these buildings will have to be reconstructed or patched up, although only erected about ten years ago.—The usual tinkering is going on at the old-fashioned Island Bridge Barracks, which it would be cheaper to sweep away altogether and replace by modern buildings. The engineer officer in charge of this work is seldom at the office, and the assistant surveyor really works the division. In building the new mess-room Mansfield stone was specified instead of a cheaper and equally good Irish stone.

London.—The barracks in London bristle with examples of incompetence ; and the unsatisfactory drainage of the Wellington Barracks, Knightsbridge Barracks, &c., is well known. "Nothing is sacred to a sapper," not even the historic Tower, where a hideous brick barrack was put up in close proximity to and within the walls of our ancient fortress. Surely some architectural style might have been used under such circumstances.

Salisbury.—About 600 iron huts have recently been erected on Salisbury Plain, yet the roof-ventilators let in snow and rain. To rectify this will cost £20 per hut, or £120,000 altogether. A contract has now been entered into with a Wolverhampton firm of builders to provide barracks for eight battalions of infantry, and the contract amounts to a million!

Sheerness.—Garrison Point Fort at Sheerness was set out in a wrong manner. The Royal Engineer officer who laid it out, instead of setting out the magnetic deviation to the proper side, doubled the error and set it out the wrong side of north. One gun is useless. Another new fort at Barton's Point has position-finding towers on either side which can be seen miles out to sea, so that the enemy has only got to shoot between these towers to hit the fort.

Singapore.—A general muddle was made of the barracks put up about five years ago, and the same system is going on. The colony paid for the buildings which were erected for the native or local troops, but the designs and superintendence were carried out by the War Department. There were actually separate contracts for the brickwork and part of the timberwork, another for the doors and frames, another for ironwork, &c. The result was appalling, as the brickwork had to stand still till the frames arrived, the ironwork to wait on the stonework, frames were made by mistake too large for the intended openings, and on one block a climax was reached by letting out a part of the flooring and joists to one contractor and the remainder to the building contractor. Bolts were put on the outside of latrine doors, scaffold poles from the lower floors were allowed to run through the concrete of the upper floors, &c., &c.

Southsea.—The Cambridge Barracks were sited so as to face inwards towards the barrack square, instead of outwards to the road as shown on the drawings.

The foregoing instances and those given previously by your other correspondents are sufficient to show any person that the department needs completely reforming. In 1883 returns called for by General Sir Andrew Clarke, R.E., Inspector-General of Fortifications, demonstrated that the cost of designing and superintending the erection of barracks amounted from 12 to 25 per cent. of the cost of the works executed. By a letter dated March 7th, 1899, the War Office announced that Sir John Taylor, Chief Surveyor of H.M. Office of Works, had been asked to inspect barracks and advise upon their construction. He only inspected a few, and his report was not published. In any case, he could only see the outside of things, and would know nothing about administration or staff or scandals, on which he was *not* asked to report. Of course his perambulation was a farce and a mere blind, so that the Royal Engineers could hoodwink outsiders with his congratulatory missive. Royal Engineer officers generally lie low and say nothing, but sometimes one is found to be candid enough to give his private opinion. For example, Colonel B———, Commanding Engineer at Portsmouth, when he came on the works, said: "Oh, I suppose it's all right. I know nothing of buildings." A Division officer once stated: "There are lots of regimental officers who are better military engineers than we are. Here I am pitchforked into a department of which I know nothing after years of military life."

Many of your readers would like to know the names of the civil architects who really design our barracks and for whose work the Royal Engineers get the credit. Here are a few:—The late Mr. J. Mecheleu Rogers, A.R.I.B.A., who designed the whole of the new Clarence Barracks and Cambridge Barracks at Portsmouth; Norwich Regimental Depot; Grangegorman Barracks, Dublin; and barracks at Aldershot, Colchester, Dover, &c. Mr. Walter Tregellas, Mr. H. O. Cresswell, Mr. Meunie, Mr. G. Rayner, Mr. G. Simmons, Mr. Ingress Bell, F.R.I.B.A., &c., formerly employed at the War Office. Among those now employed may be mentioned Mr. T. Rogers Kitsell, A.R.I.B.A., architect of the new barracks on Plymouth Citadel; Mr. Thomas Davison, A.R.I.B.A., architect of the Aldershot Hospital; Mr. T.C. Yates, A.R.I.B.A., architect of the Curragh Water Tower; Mr. W. Blount and Mr. Mally, designers of the Holywood Barracks, Belfast; Mr. J. C. Dewhurst, A.R.I.B.A., Mr. R. Temple, Mr. H. Roper, Mr. J. Walsh, Mr. J. Mitchell, Mr. J. S. Rogers, Mr. H. Hughes, and scores of others stationed all over the country at various military places. All these professional men are merely called "draughtsmen," and are barely mentioned in the Regulations for Engineer Services lest somebody might be too inquisitive. Their pay is very poor and varies from 6s. to 12s. (in a few cases 15s.) per day. If the Royal Engineer Department does not need reform I do not know which branch of the Public Service that does.—Yours truly,

REFORMER.

Horace Walpole's Villa at Strawberry Hill.

To the Editor of THE BUILDERS' JOURNAL.

TWICKENHAM.

SIR,—Allow me to correct the reply given by "G. A. T. M." to the enquiry on this matter in your last issue. Pope's Villa and Walpole's Villa are two separate houses, not one place as stated by "G. A. T. M." Pope's Villa (the residence of Mr. H. Labouchere) is on the road—Cross Deep—which extends from Twickenham Town Hall to St. Alban's Church, Teddington. Walpole's Villa is on a turning out of this road in the direction of Strawberry Hill Station. About five minutes' walk separates the two places.—Yours truly,

ALFRED BURGESS.

Designs for Proposed Houses.

To the Editor of THE BUILDERS' JOURNAL.

LONDON, N.W.

SIR,—I was much struck with the designs for houses at Pinner and Ealing published in your last issue, as they so well represent the present idea of rural domestic buildings. My principal, however, is an old stager who is always talking about the work of the great men of the past and the desirability of aiming at noble and monumental architecture even in its simplest form—a cottage. But when I begin to practise on my own account I want to make money by following the vogue ("craze" he calls it); and when I ventured to ask what he thought of these designs he laughed, and said: "Bless me, boy, can you not see they are very clever caricatures published as warnings what to avoid if you would help to raise architecture out of its present deplorable condition!" And then he went on: "You must remember some former caricatures in the BUILDERS' JOURNAL where there were clouds formed of ink lines $\frac{1}{16}$in. thick, supported on the chimney-pots and the funny trees—clouds such as you saw in some of the recent R.I.B.A. competition exhibits. It is all done to show you what to avoid, and you should be grateful to the modern draughtsman for the lesson." Sir, I don't know what to think of it, or of him. Is he "kidding" me, if you will pardon the colloquialism? How am I to know when a "goak" is intended?—Yours truly,

A PUZZLED TYRO.

To the Editor of THE BUILDERS' JOURNAL.

EDINBURGH.

SIR,—I am greatly concerned about the design for "The White House, Ealing," published in your last issue—more especially about the elevation (whether back or front, one is left to imagine!). Is this meant for students to study? Is the future to see all rules of proportion and ideas of symmetry discarded, and what might at least have been inoffensive reared up into an unshapely-looking mass—as, say, this elevation? What shall we say of lopsided gables; windows of all shapes and sizes, if possible at different levels—half-a-dozen at least in a row and the remainder of the wall a dead mass of red, white or perhaps blue plaster-work; chimney heads like primitive factory stalks, surmounted with cans taller than the length of the windows; roofs designed principally to supply the cats of the district with a rendezvous? As to the draughtsmanship—should we (students) cultivate a taste for this style, and then endeavour to acquire it? Is high-class printing the most difficult to read? When preparing drawings of this type, are the shrubs and tubs, &c. (not to mention woods and thickets) supposed to be included in the estimated cost?—Yours truly,

ONE OF THE YOUNG MEN.

Bricks and Mortar.

APHORISM FOR THE WEEK.

The simplest and least-embellished edifice, if it have the merit of just proportion, will produce a satisfactory impression; whereas the most decorated buildings, if devoid of proportion, can never be beautiful.—MILIZIA.

Some Old Tapestries. AT the Victoria and Albert Museum, South Kensington, one of the best of the tapestries from Hardwick Hall is being exhibited for a short time (by permission of the Duke of Devonshire) in the Tapestry Court now that the necessary repairs and restoration to its original form have been completed. This tapestry is probably one of the most magnificent of its kind in existence. Its actual origin is unknown. This portion of the Hardwick tapestry has a romantic history. Bess of Hardwick finished the Long Gallery—the longest room in England—in something like haste, and covered the bare piers and deep embrasures of the windows with hangings made by cutting up into strips the tapestry from old Hardwick Hall. The Duke of Devonshire has had these strips taken down, cleaned and reconstructed; when it has been found that they make up into four complete pictures, forming a consecutive series of "verdures," or scenes of hunting and sport of every kind. The piece now exhibited is about 15ft. in height by 35ft. in width. The colours are wonderfully well preserved. The labour of restoration—or, more correctly, remaking, for nothing new has been introduced into the design—has been excellently carried out by members of the Decorative Needlework Society, 17, Sloane Street, under the direction of Miss E. Gemmell. There are about forty threads of warp to the inch, and the ends of each of these had to be drawn out along the sides of each cut, matched together, spliced and then replaced.

The late Mr. F. W. Hornblower. THE death took place on December 31st, at his residence, 58, Park Road, South Liverpool, of Mr. Frederic W. Hornblower, architect, after a long illness. Deceased was the eldest surviving son of the late Mr. Lewis Hornblower, with whom he was associated in practice for many years in Liverpool, and who died in 1879. He was articled to his father in 1864. Mr. Hornblower ceased to take an active part in his profession about two years ago in consequence of continued ill-health. The deceased, who was a native of Birkenhead, had achieved considerable distinction as an architect. He was associated with his father in the laying-out of Sefton Park, Liverpool, 375 acres in extent—the most extensive park since Hyde Park; and their joint plans were awarded the second premium for designs for similar work at Roundhay Park, Leeds, over 400 acres in extent. The deceased was also successful in taking the second place with the plans which he submitted in conjunction with Mr. Francis Usher Holmes for the Government Museum of Natural History, National Library, and School of Art Buildings at Dublin in 1885, the first place being taken by an Irish architect. He gained with his father the first premium in the competition for the enlargement of Liverpool Corn Exchange Buildings, and also the second premium in the competition for rebuilding the Liverpool Stock Exchange. In 1886 he was awarded the first place for municipal abattoirs at Birkenhead, and the second premium for laying-out the Kidston Hill Estate, Cheshire, for Mr. Vyner (over 300 acres). He carried out with his father a very extensive "model" village on fireproof principles at Millom, Cumberland, for the Hodbarrow Mining Company, and laid out with him a building estate some hundreds of acres in extent near Preston. The late Mr. Hornblower was also entrusted with the execution of a large amount of private work, among others by the members of the Laird family, Lord Brassey, Sir Thomas Brocklebank, Sir F. G. Hesketh, Bart., &c. He also took a prominent part some years ago in the reconstruction of the Liverpool Architectural Society, of which he was for eight years hon. secretary and subsequently a vice-president.

THE USES OF MORTAR AND CONCRETE.*

BY WILLIAM WATTS, M. INST.M.E., F.G.S.

LIME is the oxide of a metal known as calcium, and in combination with carbonic acid gas exists in great abundance in the earth as chalk and limestone, known to chemists as carbonate of lime. Before it can be made into quicklime, however, it must be burned in a kiln and forced to part with its carbonic acid and water. It is then said to be anhydrous, that is, waterless. Before mortar can be made of burnt lime the lime must be slaked by restoring to it the water which was roasted out of it in the kiln, and must afterwards be mixed with sand, and further allowed to absorb carbonic acid from the air. During this chemical combination it becomes harder by forming silicate of lime, and serves to bind together masses of masonry and brickwork in that mysterious manner known to us all. It requires longer to harden or "set" in thick than in thin walls, but is all the better for setting slowly if good material be used.

Lime was unknown to the ancients, and was used but sparingly in buildings erected three hundred years ago in England. The earlier Greek, Egyptian and Roman buildings were constructed without it; probably the discovery had not then been made, and history is silent as to the period when mortar was first used in building. It was first employed in the East and gradually found its way westwards as civilization advanced. The use of mortar did not introduce a better class of masonry, of which we have evidence in the cyclopean structures of the Greeks and the older aqueducts of the Romans. It would be introduced slowly, and long years would elapse before it came into general use owing to the difficulty of procuring its constituents, as is evidenced in the early history of the art of modern building.

The use of mortar enables rubble or undressed stone to be more generally employed and the middle of walls better filled. It saves labour by enabling masonry not squared true on the bed to be set level; and it protects the arrises of the lower courses of a building from being broken, as the weight of the superstructure is more slowly applied. It requires very great care to dress ashlar true on the bed to take even bearing and to be made weatherproof unless the walls are made very massive, as was the custom in former times.

Hydraulic Lime Mortar.

Eighty years before the birth of Christ, Vitruvius is said to have used mortar for setting under water, but we have no evidence to show how far it was successful as a hydraulic lime, nor have we any authentic evidence that he understood the chemistry of lime. The properties of lime for setting under water remained unknown until the middle of the eighteenth century, when Smeaton first gave an impetus to its use. He saw more clearly than any other engineer before his time what was required; and as his works remain lasting monuments of his skill, he is, I think, justly entitled to be called "the father of civil engineering." The manufacture of cement, however, is not thoroughly understood even to-day. From time to time we read in our official journals of improvements being introduced in compounding and calcining, and in the selection of more suitable machinery for grinding, in order to produce a cement which will strengthen with age. In the use of cement opinions vary, and the old battles of theory versus practice are still being fought as fiercely as ever by engineers and architects, not only in the professional but in the daily papers. We are greatly indebted to the late Dr. Dalton for his researches and consequent improvement of our scientific knowledge of the art of making lime.

Mixing, and the Use of Mortars.

My remarks on mortar refer to slaked lime reduced to a paste and made ready for mixing with sand. The practice of mixing mortar varies considerably, but engineers who have studied the action of hydrates know that rich limes require to be exposed to the air before being used, to enable them to take up the carbonic-acid gas present in the air and water, and in order that they may get rid of the unslaked particles and gain strength. When thoroughly cooled, both lime and cement lose the power to swell and lift masonry; but the exposure may be too long, in which case it weakens the material. Cements "blow" in consequence of too much silica being mixed with the alumina to form the compound; the blame then rests with the burner, and not with the engineer or architect responsible for the works. I have known brickwork set in cement swell in a wall three weeks after setting, even after the cement had cooled in the shed for six weeks. This is an exceptional case, however; but experience is based on rare occurrences, and the retentive mind will profit by them. As a rule, the lifting acts slowly and to a less extent when the cement is mixed with sand. There are no tests for limes and cements by which the quality may at once be ascertained, and engineers in charge of public works have to fall back upon their experience, a faculty sometimes wanting in the younger members of the profession.

There are several testing machines in the market for ascertaining the tensile and compressive strains of cement, but they do not tell all that is required to be known, and, like some wordy specifications and tabulated figures one sometimes sees, are of little practical value. The composition of cement varies considerably in spite of all the care exercised by the manufacturer in producing it. It is affected by age and percentage of residue, and weighs less in proportion to the degree of fineness after sieving. The addition of sand weakens cement-mortar. Fine sand of equal value and quality is better than coarse sand, and shows higher tensile and compressive strains. The following table, copied from Trautwine, shows the extent to which sand weakens cement :—

Sand -	0	½	1	1½	2	3	4	5	6	7	8
Strength	1	2/3	½	·40	1/3	·30	½	1/5	1/6	1/7	1/8

Both cement and lime mortar made in the proportion of 2 to 1 may be relied upon when proper care is observed in the mixing. An inferior quality should not be used in exposed situations. Cement-mortar is rarely used in buildings of a temporary character, but permanent work of any kind is worth doing well. In setting ashlar and bricks the beds should be made clean and moist before bedding them, in order to induce proper adhesion of the mortar particles; the surfaces are none the worse for being left rough so long as they are dressed true. Common mortar should never be used in damp situations, as it absorbs moisture freely, and does not harden, but remains rotten, and in course of time drops from the walls. The practice of pointing with inferior material is a mean way of finishing work, and should not be encouraged. It is much better to use good mortar set flush to the front and then pressed firmly in the beds with a suitable "jointer." Mortar is much impaired by frost, and should not be used when "Boreas" blows keen over the land. Neat cement is less affected, but even this is more or less disintegrated if employed in exposed situations. Cements and lime should not be mixed together for outside pointing; they make a good paste for handling with the trowel, but the rate at which the two ingredients set is not equal in point of time: the molecules of the stronger pull the weaker ones asunder, and both are affected, to their disadvantage. Roman cement makes a better paste for pipe-jointing than Portland, not because it sets harder, but because it is more adhesive, and therefore less is wasted in the work. Referring to hydraulic mortars in general, no more should be mixed than is required for immediate use. Its primary strength cannot be recovered on mixing a second time. It will harden, however; but it is "short," and disintegrates sooner than when manipulated once only. Brick-setters prefer mortar worked up a second time when using wet bricks; but after the crystallising forces are once brought into play, they lose their mysterious power if checked in their silent building up, and do not regain their normal strength.

Mortar is weakened if too much water be used in mixing it, but account must be taken of the season of the year and the quality of the sand, lime or cement used, all of which concern the handling of the mixture. It is difficult to prepare a mortar to suit every class of work and weather; and while rules may be laid down as a guide in preparing the mixture, its setting properties must be judged by use on the works. Good mixing is important, and the selection of clean sand and water should be insisted upon; mine-dust and well-ground cinder ashes are good for masonry and brickwork generally, but they are not recommended for use below ground. The rich or "fat" lime is often spoiled in slaking for the want of sufficient room and water and energetic stirring. Buxton lime swells to about three times its original bulk in the process of hydrating, and unless the slaking pit be made large enough, dry lumps remain in the paste and cause a waste of material. One rarely sees the walls of a newly-plastered house without lime blotches in them. These are the pieces of unslacked lime asserting expansive power in the opportunity now afforded them of taking up additional moisture. Properly-slaked lime will keep for centuries and improve with age, especially if kept covered with water; builders generally very much neglect slaking and making the best use of lime. Labourers of the lowest intelligence are frequently employed to mix and proportion the sand and lime without proper gauge-boxes being provided. In my opinion the municipal authorities of every town should provide and maintain public lime-slaking works, where good lime properly seasoned could be obtained by local builders, and the use of no other material should be sanctioned unless it were proved to be of standard quality. This suggestion may be objected to, but surely it is the duty of everyone building homes for the people to erect them substantially and make them worth looking at and fit for occupation. The Romans had a good municipal rule bearing upon this subject. They made it compulsory on every builder that no lime should be used in any building unless it had been slaked at least three years. No wonder they had such good walls, fit to receive and retain any colour of paint placed upon them. There are particles in all limes which require longer time to slake than others, and unless the whole be thoroughly hydrated it swells, as previously pointed out, and defaces the work. Whether it is better to use steamed or slaked lime must be left to the judgment of the architect; but no lime should be used in a heated condition either in the foundation or the elevation of a building. Good material and work can never be put in the wrong place, seen or unseen, and this idea cannot be too strongly impressed upon the minds of all builders.

In masonry walls grout cannot be too freely used for binding together the "filling in" of the middle; the fillings, however, should not be put in dry, but each stone should be carefully bedded in mortar before the grout is poured on. The grout should be made of the mortar of which the wall is built, and of a consistency which will enable it to flow freely and fill the interstices that may have been missed by the trowel. The liquid should be poured out of a circular spout and carefully stirred while flowing (this mode of delivery steadies the flow, confines it, and assists in regulating the quantity required). Where great density is necessary, iron borings may be added with advantage, not mixed in the fluid, but hand-sieved upon it as it leaves the spout. These instructions may seem unnecessary to some persons, but careful observations and deductions have shown me the wisdom of paying close attention to small details. Every useful piece of work intelligently designed and conscientiously executed is a monument of a lasting character for which our descendants will give thanks. My experience, which is now a long one, has been confined to the construction of important waterworks; and architects engaged in making small towns great ones may look upon some of my suggestions as difficult to carry out in their profession. In the main my work has been in the ground and in building to resist the static pressure of water; your work is, for the most part, built above the surface, exposed to atmospheric agencies and the gaze of man—indeed, for his dwelling-place and social intercourse.

Concrete.

During the last twenty years some of the advantages of a freer and more extensive use of concrete have become patent to the profession. In my opinion, however, its adaptability for various classes of work entitles it to much more extensive employment. I do not advise its use in elevation above the ground, but freely in works below, where the matrix seems to find its natural place. For foundations in damp situations concrete has no equal, but it looks cold and uninteresting in elevation, even in promenade sea-walls. I would use it freely in cellar foundations, for floor and side walls, and I would also employ it freely for arch-sheeting, not in preference to ashlar quoins but in preference to bricks. It lends itself to this class of work admirably, and is much cheaper when suitable concrete-stone is at hand for making it. Three of the arches on the Langsett tram-line are turned with it, also the intermediate arches at Mortimer Road resting on steel girders; and although a 30-ton locomotive has daily passed over this 30ft. span bridge for nearly four years not a hitch has appeared, although critics anticipated a failure. There is probably no structural bond so good as well-set brickwork, and no mass so solid and impervious as concrete. It is extensively used for large engine-beds, and is replacing ashlar masonry for this class of work; it is less dense, however, but this may be an advantage, as the continued vibration may find a more easy cushion on which to react and thus prolong the lives of prime movers. I know no better material for light-arching and footbridges, and it has advantages for collieries; if made from hard shale and cinder ashes, it is most suitable and economical for use in the construction of temporary erections.

---

* A paper read before the Sheffield Society of Architects and Surveyors on January 9th, 1902.

Cement will bind and amalgamate with all kinds of durable materials, regardless of colour or shape, if they be broken small enough and provided with sufficient fine admixture to form a gelatinous mass. Burnt-shale concrete is an excellent ingredient for many kinds of work which architects and engineers are called upon to execute. It only requires bringing to the front and giving a fair trial to commend itself to the profession generally. I do not, however, recommend it for work having to resist great compressive strains, but in breast or burr walls, for backing, and similar less important jobs where the facing is of stone or bricks. Backing of this kind is infinitely better than coarse rubble or damaged bricks carelessly built regardless of bond or bed. Some of the walls built in front and at the back of gentlemen's residences, supporting as they do in many cases garden plots and lawns, are out of plumb-and-line for the want of better backing, and because they have been thrown together rather than built. Nothing looks more distressing than well-dressed wall stones shabbily built and oversetting or bulging out, as the case may be, simply for the want of a little more care in building and in the selection of the material for both sides of the wall.

Burnt-shale made into concrete as suggested should provide a good foundation for street-paving. There is an abundance of it available where collieries exist, and if given a fair trial I am sure it would prove satisfactory. The refuse from a town destructor should also make excellent concrete, especially if a little clean sand or gravel be added to consolidate the mixture. It is wasteful to tip broken bricks, stone scapplings, pots, glass bottles and garth iron down the spoil tips of any large town. If collected, this waste product, when cleaned and broken sufficiently small, could be used as concrete for the foundations of many buildings, and would form a more solid bed than the dry rubble and rubbishy bricks one sometimes sees used for this purpose. I have often thought that the waste slag from ironworks could be utilized for the foundation of roads, with a thin layer of fine concrete placed upon it to form a level bed, or even fine broken stone where the traffic is slight and cost a primary consideration. I have noticed that the president of your Society has used iron slag in paving a river-bed at Stocksbridge, which seems to answer admirably, and I am not sure whether he has not also used it for backing in a breast wall. This class of waste material is like a wayside flower—too common to be noticed, gathered and made use of. "If the stars were seen once in a thousand years how men would believe and adore, but every night come out those envoys of beauty, and light the universe with their admonishing smile."

I come now to consider the more important use of concrete in large engineering undertakings, and mainly in concrete trenches and embankments for reservoirs. English hydraulic engineers have been slow in adopting concrete as a foundation material for deep trenches. Why this is so I do not know; either extreme caution has been the motive, or want of experience in its use. In every new departure from old and tried customs cautious men proceed slowly. Caution is a virtue if not carried too far, when it becomes weakness. Men of genius try new methods, and deserve our thanks and sympathy even if they fail. Concrete trenches for reservoir embankments are better and much cheaper than puddle trenches. (The lecturer here referred to a diagram showing three typical trenches adopted by present-day engineers. One was the old type of puddle trench, without any protecting cradle of concrete; another, the form of trench adopted in the Little Don Valley works; and the third, a modified form of the other two, in which the puddle is sandwiched into the concrete at the bottom, and concrete walls are carried sufficiently high on each side to protect the clayey matrix from the action of springs which exist under considerable static pressure in nearly all trenches. The concrete trench being the cheapest, the lecturer compared the cost of the other two with it, and found that a trench similar to the first costs 34 per cent. more per lineal yard, and one similar to the third 46 per cent. more; in which comparisons a length of 200yds. was estimated, including the cost of timber, cement, stone and labour of every kind pertaining to the work. The trench was 60ft. deep in each case. The first cost £159 per lineal yard, the second £119, and the third £174. These details were given by the lecturer more particularly because it is generally understood that concrete is more costly than puddle, which is not a fact when the circumstances of the work and situation are taken into account.)

Concrete below the surface of the ground has many advantages over its clay rival, especially in bad ground where springs exist and have to be driven back into the solid measures on either side. A concrete trench is opened out sooner than a clay trench twice or three times the width, and the refilling may commence at any part where the substrata are bad or a large influx of water exists. The concrete matrix, when properly treated, becomes as solid as masonry and as impervious as clay. At whatever angle rock may dip on either side of a trench it cannot force its way through concrete, as it has been known to do in trenches of clay, which have had to be taken out again and a fresh start made with the work. These are a few of the advantages of the use of concrete over clay puddle in the trench of a reservoir embankment; and others could be cited. I recommend great caution in arriving at a decision as to the respective merits of a concrete dam across a valley in lieu of an earthen embankment. It is easier to make and contains fewer details, and though it occupies longer time in building than an earthenware embankment it is not any more enduring. The geological features of all valleys are not favourable for concrete dams being erected in them. Depth is always an element of danger in the storage of large volumes of water, and an engineer is not justified in incurring risk for the sake of novelty, however tempting the site may appear. Ideas and desires in these matters should be subservient to experience in every detail. A good reservoir, whether constructed of earthwork or concrete, is worth more than all the jewels a city contains, and the choice of site and material to be used require serious thought and consideration; their selection should not be entrusted to inexperienced hands. I am not sure that the Pennine buttresses in the deeper valleys above the saturated level are at rest for all time, at least on the dip side. I have observed that slow movements have occasionally taken place in masonry of the best possible character built on rock foundations. Cracks have appeared in an irregular manner for which a slipping and not a subsiding movement only can account. Architects know very well that any subsidence in a foundation is more intensified and apparent in good work than in bad; and this has suggested the idea of keeping the top of the concrete in the trenches in the Little Don Valley well below the line of thrust of lateral movement, and also below the thrust of the made part of the embankmen This is not the time or place to enlarge up this very interesting geological phenomenon. daresay some of the Sheffield architects w have noticed that buildings on one side of valley are more liable to give way or crack th on the opposite side. This observation is wor making for the value of the information it fu nishes in the selection of sites for buildin especially lofty ones.

Concrete and masonry barriers represent t latest fashion of reservoir-making in Englan and the gloss of novelty still remains. Th were practically unknown half a century ago, sa to a few hydraulic engineers, but are veneral structures in the East. Where rock dominat especially the older deposits; clay and earthwo are scarce; drainage areas large; and where is found necessary to make the whole leng of the dam into a waste weir; such sites a favourable for the use of concrete structur In very dry climates earthwork embankme built on a large scale are a source of dang owing to the evaporating power of the hot s and dry winds causing deep cracks to form in t outer slopes, which get filled with rain when comes and induce slips. In humid climat like our own there is no danger of this kin heavy dews forming on the grassy slopes prote them, and in the driest months of the m droughty year we have some rain. Earth embankments are more ancient than concre ones, and those built by the ancient Egyptia still endure.

Wise engineering consists in utilizing t available material found in the district in whi the proposed work is to be erected, wheth that material be solid rock or earthwork. earthen dam is cheaper than one made of co crete. It is sooner brought into use; and, as t president of the Institution of Civil Enginee said in his inaugural address last Novembe comparing the numbers of the two forms of da in use, fewer failures have taken place in t former than in the latter type of embankme Before an embankment of any kind can made much detailed work has to be done, a it is the attention paid to details that mak every work a success, more particularly, believe, in waterworks. You may have go designs and employ the best material, but carelessly put together the genius of the man diverted and good material shamefully waste So far my remarks have mainly referred the use of concrete; the remainder of paper I propose to devote to the details preparing concrete.

Stone-Breaking.

Stone broken by machinery is much bett than hand-broken stone, and costs considerab less. It is more uniform in size; and when t breaker is carefully attended to, it provides t necessary amount of sand requisite to form t concrete matrix. The best stone for hydraul concrete is the millstone grit, or rock of similar texture—the coarser the grit the bette but it should be free from dirt. If claye matter adheres to the stone it should be scrape off, and if necessary the beds should be washe Old fence walls and rejected bricks make goo concrete. It is not necessary to provide ver hard material to secure impervious concrete in reservoir trench; but the hardest stone shoul be provided for sewers, tunnels and sea-wal where there is surface friction to be resiste The hardest class of stone should also be used i arching, forming footpaths, barn, shippon an stable floors. Flint gravel makes the hardes and perhaps the most durable concrete, but it i expensive and difficult to obtain in the north England. Some engineers screen the stone a it falls from the breaker and wash the san before using it, but this seems costly an unnecessary when the rock in bulk can b obtained clean. The dust produced in breakin forms a very small percentage of the matrix, an in my opinion improves it when required fo impervious work. The finer interspaces ge filled, and in this respect the dust seems to ac beneficially.

For water-tight concrete the stone should b broken in cubes no larger than will pass throug a 2in. ring, and should contain plenty of sand For foundations in which the impervious character of the matrix is no object, larger stones may be used, but it is a question whether the

smaller are not better, and it is wiser to err on the safe side. Where compressive strains only are to be encountered, clean dry stone may be employed in 3in. layers, pounded and grouted with a cement liquid. For bridge-pits, lofty chimneys and buildings better foundations cannot be formed. It must be understood, however, that I am speaking of foundations below the ground, where compressive strains only are brought into play. Where large masses of concrete are required, blocks of stone called "plums" are frequently embedded in it to reduce the cost.; these "plums" should be well cleaned and laid the best bed down in the matrix whilst it is in a soft state, and care should be taken that they are placed well apart so as to ensure that the soft material covers and overlaps them. "Plums" increase the density and stiffen the mass, and there is no objection to their use when the work is properly done. When the stone is broken by a stone-breaker it should fall into a waggon or skip and be taken to the mixing stage and manipulated at once.

The mixture then has its proper quantity of sand, which cannot be secured when run to spoil and subsequently refilled, owing to the stone separating from the sand, which is unavoidable in a large heap. In executing work of any kind the fewer and simpler the operations the better; thus labour also is saved, an important consideration in large public works.

Concrete Mixing.

It is necessary that all concrete should be carefully and properly mixed. Next to the use of good material, this is most important. The mixture should be thin, placed in position in this state, and never disturbed afterwards. Setting begins at once, and the crystallizing forces want free play, which they cannot have if the work be disturbed by men passing over it. The broken stone and cement should be measured in [illegible] provided for the purpose, and as much clean water used as the matrix requires to form the proper consistency—more rather than less. The mixings should not be too large: 20 cub. ft. of stone and sand and 4 cub. ft. of cement form a good mixing sufficiently large for a gang of six men to prepare and place in position before setting begins. The slow-setting cement gives more time and insures a better conglomerate, especially if the mixing stage be some distance from the place where the matrix is required. In watering the mixture a jet or rose should be used, as it moistens the material more evenly than when water is poured on it from a bucket. During the last turning the mixture is much improved by kneading with a light pick or shovel, the object being to thoroughly amalgamate the whole. The most trustworthy men should be employed for this class of work; they soon get accustomed to it and learn from experience to use their reasoning powers as well as their hands, and if properly paid they may generally be depended upon to do their duty. For more than twenty years I have been in the habit of letting the mixing of concrete to specially-selected gangs of men, and have never had cause to regret. The men also seem to prefer taking the work in this way. Inspectors are usually employed on large works to see that directions are carefully followed; but as a rule a good English navvy will be loyal to employers who are worth serving.

Concrete should always be mixed on stages provided for the purpose, which should be kept clean and well supplied with water. In levelling, the layers should not be too deep, and if the work has been at a standstill for a few days the surface of the old layer should be chipped rough, swept clean, and grouted before work is resumed. When the chipping is properly done the junction of the old and new layers cannot be detected after the whole has had time to set. In trench work vertical faces may be left for convenience, and when the junctions are carefully made they do not show and are perfectly water-tight. Concrete should not be tipped from the stage into the foundation, but placed in position as a homogeneous mass, whether required for foundations only or as a water-tight core. In deep trenches it is usually dropped down a wooden shoot, about 12in. square, to a platform, and afterwards shovelled into position. This is a very convenient way of letting it down, and the mixing is improved by the fall. The shoots, however, require frequent attention, or they get choked up by the fine material adhering to the sides, but this may be prevented by pouring a little water down after each delivery. In mixing, the material is reduced in bulk about 12 per cent., and this factor requires deducting in estimating the finished work. It is generally believed that Portland-cement concrete is far superior to hydraulic-lime concrete. For water-tight trenches I am bound to say that lime-concrete gives as good results, if properly manipulated, at about one-half the cost, and is easier to mix. Where, however, the matrix is placed in immediate contact with water in motion, or is required to resist compressive strain immediately, cement-concrete is superior; but in the course of a few months there is very little difference in the strength of the two mixtures. 4 to 1 lime-concrete gives as good results as 5 to 1 Portland-cement concrete for structures above ground, and it has also the advantage of being slower setting. I am aware this opinion is not generally held by the profession; but I am stating the results of many years' experience in the use of the two materials.

Let us see how these two concretes compare as regards costs.

Cement at 42s. per ton and 85lbs. per cub. ft. works out as follows:—

$$\frac{85 \times 42 \times 27}{2240} = 43\text{s. per cub. yd.}$$

Hydraulic lime at 21s. per ton and 63lbs. per cub. ft. gives the following result:—

$$\frac{63 \times 21 \times 27}{2240} = 16\text{s. per cub. yd.}$$

Cement-concrete at 5 to 1 requires 5 4 cub. ft. of cement per cub. yd. of matrix. Lias-lime concrete at 4 to 1 requires 6·75 cub. ft. of lime per cub. yd. of matrix. In round numbers, cement costs 1s. 7½d. per cub. ft. and lias lime 7d. There are 26·07 cub. ft. of cement and 35·00 cub. ft. of lime in a ton. A cub. ft. of Langsett grit rock weighs 154·5lbs. and has a specific gravity of 2·48. Concrete made from this rock weighs 138·30lbs. per cub. ft., and possesses a specific gravity of 2·22. Lias-lime concrete at 4 to 1 is certainly more fat than cement-concrete at 5 to 1. It contains 1·35 cub. ft. more cementitious material per cub. yd. to fill the interstices of the stone and sand, which is a decided advantage in its favour, although it is much longer in setting. In dry weather jelly-concrete requires 34 galls. of water per cub. yd. of concrete.

Builders' Notes.

The York Master-Builders' and Contractors' Association held its annual meeting last week. Councillor Mansfield and Mr. C. Prudames were re-elected president and vice-president respectively.

Mr. Stephen England, builder and contractor, of St. Annes, died recently in his sixty-eighth year. His firm executed much important work in the district. He was the first chairman of the St. Annes branch of the Master-Builders' Federation.

"Lockwood's Builder's and Contractor's Price Book."—The edition for 1902 of this valuable work has just been published. All the popular features are retained, and the prices have been revised and brought up to date. Its value as a reference book we have referred to before, and we need give no further commendation. It is published by Messrs. Crosby Lockwood & Son at 7, Stationers' Hall Court, Ludgate Hill, E.C., price 4s.

Messrs. G. B. Kent & Sons, Ltd., of 75, Farringdon Road, E.C., have issued their catalogue for 1902. The prices quoted are slightly easier than in 1900 and 1901. It is interesting to note that on January 1st, Mr. Sacheverell, who entered the service of the firm seventy-four years ago, called to wish the directors "A Happy New Year" on the commencement of the 125th year of the firm's existence. He was accompanied by Mr. Benwell, late foreman of painting-brush makers, who came to work for Kent's in 1846, and is now retired on a pension; so that the combined years of service of the two old employees amounted to 130 years, which must be a record hard to beat.

Engineering Notes.

Mr. James Ponsford, M.I.C.E., died at Cairo on January 2nd. He had been engaged for many years in leading positions, as an engineer, upon the construction and working of railways in European and Asiatic Turkey.

American Competition Beaten.—When the Central London Railway was constructed, all the rolling stock, rails, lifts—in fact, nearly all the engineering plant—was imported from America; and when the Company decided on some additional lifts they asked tenders not only from America, but also from some British firms, and it is quite refreshing to note that the British firm in this instance has been successful. Messrs. R. Waygood & Co., Ltd., of Falmouth Road, London, S.E., have been entrusted with this contract, being able to comply with the special requirements of the railway company. We also note with satisfaction that the lifts for the City and South London and the Great Northern and City Railways have been secured by a British firm in face of keen American competition.

South-West India Dock Improvements.—To meet the demand for more accommodation for large vessels in the Port of London, which is daily becoming more urgent, the directors of the London and India Docks Co. have for the last two years been carrying out extensive alterations and new works at the river entrance to the South-West India Dock. These works have just been completed, and the temporary dams are being removed, so that vessels 450ft. long and of a carrying capacity of 6,000 tons will be able to enter the dock by the new lock. This dock is, with the exception of Tilbury, the deepest in London, having a depth of 29ft. With its basin it has an area of 32 acres, and the quay walls are of sufficient length to accommodate twelve ships 450ft. long, in addition to a few shorter vessels. But as the old entrance lock was only 300ft. long, with a depth of 27ft. on the sill in the centre, reduced to 24ft. at the sides of the invert, it was decided to increase the length to 480ft. and lower the sill and invert to 29ft., and also to construct under the lock a sewer for the London County Council for the drainage of the Isle of Dogs, to replace an old sewer in the bed of the river in a somewhat dangerous position across the entrances to several docks. To exclude the water from the site of the works the contractors placed a timber caisson across the lock at the river end and drove a semicircular dam in the basin. This dam had a length of 360ft, and was formed of a single row of double timber piles 45ft. to 50ft. long by 26in. thick, driven 15ft. into the bottom of the basin, and supported at the top by a timber rib 16ft. wide, to preserve a true circular curve to the dam. The bottom of the basin, being composed of very fine silt and running sand, gave a great deal of trouble, and serious delay occurred in consequence of the water blowing up under the piles until the contractors weighted the bottom with a bank of sand in bags 15ft. high and tipped a bank of clay on the water side, after which the dam was perfectly watertight and stood very well. The extra pair of gates required for the extension were obtained from another part of the dock where they were no longer required. As the mud in these docks causes great inconvenience in working the gates, iron pipes connected with the sluice culverts have been imbedded in the concrete of the new gate platform, so that the act of lowering the water in the lock draws away the mud from the roller paths. The sluices are in duplicate, one set worked by hydraulic power, the other by hand in case of a breakdown. The sewer, which is 500ft. long, is carried under the lock by two cast-iron culverts, each 4ft. 6in. in diameter, bedded in concrete. These culverts enter penstock chambers 50ft. deep, built in brickwork through the centre of each quay wall, and can be closed by hydraulic sluices. The approach sewers on either side from the public road are 4ft. 9in. in diameter, and built of brickwork in tunnels which were driven through the sand. The cost of the works, including the sewer, has been about £52,000.

Messrs. Cobbetts, timber merchants, of 62–70, Virginia Road, Bethnal Green, E., have just issued their price-list for 1902.

Enquiries Answered.

The services of a large staff of experts are at the disposal of readers who require information on architectural, constructional or legal matters. Questions should in all cases be addressed to the Editor. The querist's name and address must always be given, not necessarily for publication.

Registering Houses.

LONDON, N.W.—D. B. writes: "Is there any advantage in having a leasehold house registered?"

There is no advantage whatever.

G. A. T. M.

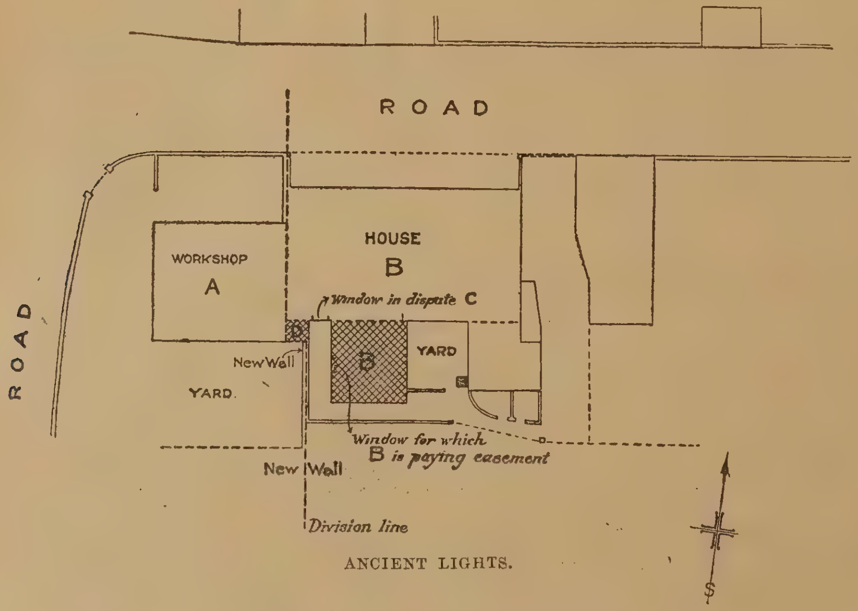
Whitening Rough-Cast.

TWICKENHAM.—BROWN MADDER writes: "Referring to my enquiry on p. 350 of your issue for January 1st, I fear from the nature of the reply to which you refer me you do not quite understand my difficulty. The rough-cast I have to treat exists and is at present a brown colour. This I wish to alter to white, and I propose doing so by giving the work two coats of lime-white. What can I mix with this to prevent the rain washing the white off?"

Lime-white is probably the best material you could use. To fix it, mix some alum with it.

Ancient Lights.

HARROGATE.—W. J. E. B. writes: "A is the owner of property to the west of the dotted line shown on the accompanying sketch, and B is the owner to the east. A proposes to erect a wall along the boundary of the two properties, the height of which will be above the window C in B's living-room. This light has been in existence for more than twenty years. About ten years ago B erected an off-shoot (cross-hatched on plan) and also a water tank over the existing scullery, marked D. They are both 6ft. higher than the top of the window C, and greatly intercept the light to it. B is enjoying light in the off-shoot by agreement with A. Can B legally prevent A erecting the wall on the ground that it interferes with his ancient light C?"



ANCIENT LIGHTS.

As frequently happens with queries of this nature, it is impossible to give an absolutely definite answer. At the same time, B evidently thought little of the value of his window at C when he erected the water tank and the off-shoot ten years ago, so that if he were to object to A building the contemplated wall now he would obtain but slight compensation, if any, as in comparison it would obstruct the light to a very small extent indeed. In all probability, if he were to test the case he would fail, under these circumstances, to obtain even an injunction against A. G. A. T. M.

Fonthill Abbey.

SOUTHPORT.—F. H. C. writes; "What is the present condition of Fonthill Abbey? Does any considerable portion of the house still remain, and is it possible to get to see it?"

Fonthill Abbey, a Renaissance building, has been very much overrated. Emerson considered it so bad that he adduced it as an instance of "the proneness of the English character to freaks." The Abbey consisted of a main block, the lower portion heavily rusticated, with an Ionic portico surmounted by a pediment, with armorial bearings in its tympanum, and of two wings of larger size, which caused the building to assume a crescent shape on plan. These wings have since been pulled down. An old archway ornamented on both sides with grotesques, a relic of one of the earlier abbeys on this site, stands at the entrance to the grounds. G. A. T. M.

Curing Smoky Grate.

WISBECH.—PUZZLED writes: "I am at a loss to discover the cause of the smoking of a 'Marlborough' grate (with adjustable canopy and Teale back) which has recently been fixed in a house. A common 9ft. iron tallboy has been fixed on the head for experiment, but with no good result. Why does the grate now smoke, whereas it used not to do so?"

Your chimney, it is evident, has not sufficient draught for a "Marlborough" grate, which utilizes so much heat that very little is available to heat the air in the chimney, as is necessary to get a good draught. The simplest remedy is to put in a quicker combustion grate, or you might try one of the many chimney cowls on the market to increase the draught.

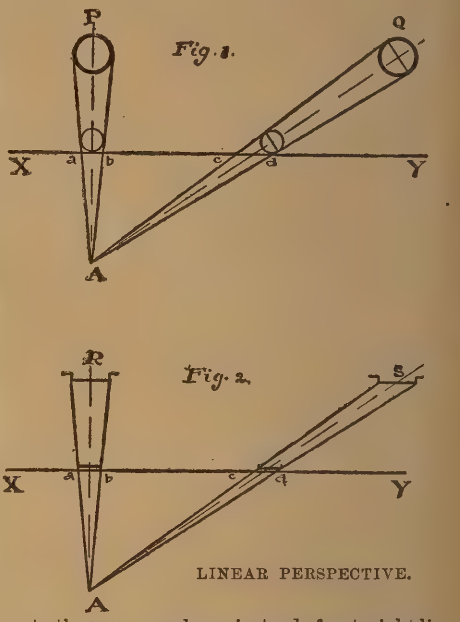
Cracks in Cemented Lake Bottom

LONDON, E.C.—NON-PLUSSED writes: "A lake is concreted with the best cement, and material of every description most carefully manipulated, and of an average thickness of not less than 6in., on solid ground. Notwithstanding this, though holding water perfectly during the spring, summer and early autumn, yet in October or during any great drop in temperature cracks open through which the water percolates and sinks away. It seems pretty evident that this is caused by contraction not only of the concrete but of the earth as it cools. For this a remedy is much desired—some substance that can be forced into the cracks when open, that will expand or contract according to the variations of temperature, so as to prevent the very troublesome leak."

We know of no substance that you can use that will expand with cold. We advise you to cut the concrete away along the lines of cracks to about 6in. on each side, and put down a layer of asphalt 1in. thick below the level of the concrete, leaving a ridge about 2in. wide along the centre, jutting up a little above the level of the top of the concrete. Then continue the cement up to the ridge, which will allow sufficient play for expansion and contraction. You will doubtless find some points of interest to you in the two articles in this issue on "Service Reservoirs" and "The Uses of Mortar and Concrete" respectively.

Linear Perspective.

HERSHAM.—R. R. writes: "Will Mr. Middleton please say why the far column Q (Fig. 8) in his book on linear perspective is not projected on to the X Y as a column instead of a straight line c d; and also if Fig. 1, columns, and Fig. 2, pilasters, are or are not correctly projected?"



LINEAR PERSPECTIVE.

Querist's Fig. 1 is practically the same as Fig. 8 in the book referred to, and his first query is therefore to be answered by pointing out that the spaces between the extreme rays from the columns to the eye at A are intercepted at the X Y by the portions of the X Y lettered *a b* and *c d* respectively. Both diagrams are correct, and it will be noticed that *c d* increases in the case of columns and diminishes in the case of pilasters, as they are further from the eye, columns being thus incorrectly rendered in parallel perspective.

G. A. T. M.

Damp Walls.

MANCHESTER.—F. B. B. writes: "Two houses in different parts of the north-west of England have sides exposed to the full force of the prevailing (south-west) wind and rain, which cause damp to get through the walls. One house is of brick and has at some time been coated with coal-tar or similar material, but this has partly worn off and is now useless. The other house is built of a gritstone, evidently porous. What would be the cheapest way to remedy the defect?"

The cheapest method is undoubtedly to renew the tarring, which would be more effective if a considerable quantity of pitch or bitumen were added and the mixture applied hot. But this, of course, requires constant renewal, and in the long run it would be more satisfactory and cheaper to use vertical slating or tiling.

Earth-Closets for Country House.

HOVE.—R. R. writes: "Please name a good work on algebra of use to an architect's assistant. What I want is a brief, compact and sensible exposition of the science, with answers especially adapted for building purposes. Also, please give plan, section, details and explanation of what you consider to be the best privy for a country house where there is no water service."

There is no book on algebra as applied to building. If you are familiar with the science as you should be, you will find no difficulty in applying the rules. With regard to your second question, an earth-closet should be used, and if you obtain catalogues from Messrs. Moule's Patent Earth-Closet Co., 5A, Garrick Street, Covent Garden, W.C.; Morrell's Sanitary Co., of Manchester; or Mr. W. F. Parker, of Oxford; you will find all necessary particulars. A privy is insanitary, and we therefore prefer not to give a design. See the article on "The Sanitation of a Country House," which appeared in our issue for November 20th last.

SERVICE RESERVOIRS.*

THEIR DESIGN, CONSTRUCTION AND COST.

BY WILLIAM INGHAM, A.M.I.C.E., M.I.M.E.,
WATER ENGINEER, TORQUAY.

FOR some years past I have been collecting material for a paper on this subject, and have now no hesitation in laying before the Association the conclusions I have arrived at.

In connection with any waterworks scheme, one of the first things which has to be considered is the position, size and materials to be used in the construction of the service reservoir. That a service reservoir is a necessity in most waterworks schemes will, I think, be agreed to by all, so that it behoves the engineer to select a site that will, if possible, give the necessary altitude, a good foundation, and the required area of ground.

The Chief Points

to be considered in connection with the design of service reservoirs are: (1) The greatest daily variation in the supply; (2) the length of time necessary to repair any defect either in the trunk main, pumping engine, or other machinery between the storage reservoir or well and the service reservoir; (3) the maximum requirements in case of fire, or of the bursting of water-pipes (as in 1895) due to frost; and (4) utilising the reservoir to equalise the variation due to intermittent pumping.

The variation in the daily consumption is by no means the same in different towns, or even in different districts of the same town.

Where there is only a single main from the storage to the service reservoir, the latter should be large enough to supply the district for three or four days—if in duplicate, from one to two days' supply will be found sufficient; but the capacity of the reservoir must depend somewhat on the length and accessibility of the main. If the distance from the storage to the service reservoir be short, it may be more economical to lay a second main rather than to build a larger service reservoir.

For pumping schemes where the machinery is duplicated, a two days' supply is generally sufficient. If the supply is delivered to the town direct from the trunk mains, a larger pipe will be required, as it will have to discharge at a rate sufficient to meet the greatest demand, but with a service reservoir this will be avoided. If the district supplied is very hilly, it can be worked in zones by separate reservoirs, the sites being fixed to give a head of not less than 60ft. or more than about 150ft. above the pavement level.

If the reservoir only supplies water to property around the hill upon which it is built, the pressure can be reduced by a reducing valve; but where the pipes run across a valley to supply property on another hill, it is not advisable to lower the pressure. The depth of service reservoirs is generally between 9ft. and 18ft, the most economical depth, considering all things, probably being within the limits of 12ft. and 14ft. Low walls are much cheaper per ft. in height than high ones, and this should be carefully considered when designing a reservoir.

For covered reservoirs the economical depth to be excavated under the original surface of the ground may be taken at from 50 to 60 per cent., and for open ones at from about 45 to 50 per cent. of the height of the wall. If the soil can be excavated by machinery, it will pay to do it if the quantity exceeds 30,000 cub. yds.; the cost then being from 9d. to 1s. per yd. The filling behind the walls should be of selected earth, brought up in 9in. layers, slightly watered, and well rammed. The embankment should be consolidated in the same way, and finished with a slope of from 2 to 1 to 3 to 1, according to the character of the material, but should in no case exceed its natural slope. Embankments settle about 1in. per ft. of depth, and enough soil should be left on the ground to bring them up to their full height after settlement. On completion, the embankment should be turfed or sown with grass seeds, but on no account should trees be planted immediately behind or near the reservoir walls.

The inlet pipe may be below, but is better above, the water-level in the reservoir. The outlet supply pipe can be controlled by a valve, either within the reservoir or behind the walls. The best practice is to place the valves in a well behind the walls, so that they can be examined and repaired without interfering with the supply. All pipes under water should have flanges cast on them to prevent creeping, and be laid in fine concrete and grout. The weakest place in a reservoir is, as a rule, along the line of outlet pipes, and unless they are carefully laid in cement grout leakage will occur.

Under certain conditions, the inlet or delivery main to and the supply pipes from the reservoir may be connected with a by-pass outside the reservoir, so that when the reservoir is being repaired or cleaned out the supply to the district can be maintained. This, however, is not advisable where the pressure in the delivery mains is high, as the fittings in most towns might be unable to stand it. On the other hand, any excessive pressure could be lowered to meet the exigencies of each individual case by means of a reducing valve. Otherwise, a dwarf wall could be built in the reservoir, separating it into two compartments having an outlet pipe from each, so that either compartment could be cleaned out without varying the pressure on the fittings to any great extent.

Before designing the reservoir, it is absolutely necessary that the engineer should make himself acquainted with the class of material he is going to build upon by making trial pits; for unless this is done failure may occur on the one hand, or, on the other hand, a costly reservoir may be constructed where a much cheaper form would be quite as efficient.

The materials chiefly used in constructing service reservoirs are concrete, brick, puddle, asphalt and bituminous sheeting. Asphalt, as a waterproof material, in the form of mortar and concrete, was used about 4,000 years ago at Babylon and Nineveh; while at Memphis, in Egypt, it was also used for keeping basements dry. Sometimes the above materials are used in conjunction with one another, but I consider that puddle is used in many cases when there is absolutely no necessity for it. For instance, to place 2ft. of puddle behind a reservoir wall with a mean thickness of 4ft., and to then make the floor with concrete 15in. thick without puddle, is bad engineering, especially where the land is subject to settlement. Where, as in some of the Colonies, it is practically impossible to obtain good workmanship, one can understand puddle being used; but to use it in any and every place is an exhibition of bad designing. Of late years concrete has been largely used for waterworks purposes, and, if properly made, it is a very desirable material. The thickness required in a reservoir floor will, to some extent, depend upon the depth of water, the geological nature of the ground, and the class of concrete used. A rough-and-ready rule for a fairly good floor of concrete alone is to make the thickness of concrete equal to one-twelfth of the depth of water, with a minimum thickness of 6in., the concrete being 6 to 1 and rendered with cement and sand in equal parts. This thickness can be reduced if either asphalt, puddle or bitumen sheeting is used in conjunction with the concrete, as shown in the examples A, B, C, D, E, F (Fig. 1).

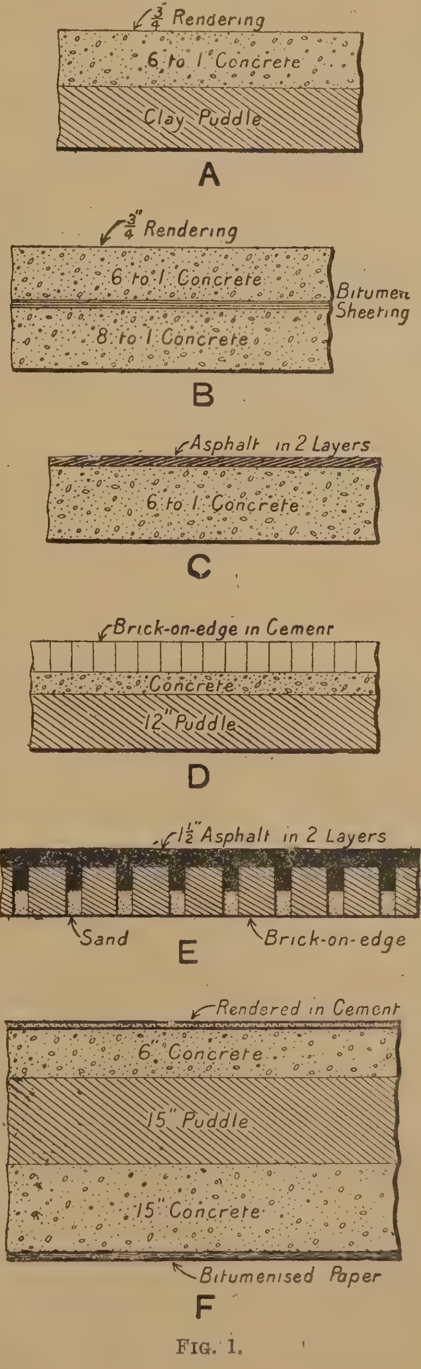


FIG. 1.

In the case of D, the brick on the surface of the concrete appears to be superfluous; and E shows a design which cannot be recommended except for cheapness. In the latter case, after the slope and bottom have been made to a proper batter, a layer of sand 1in. in thickness is placed upon it; then bricks on edge, spaced about ⅜in. apart, with the joints filled up to about one-half the depth with sand; after which asphalt is poured into the joints and allowed to run over the face, upon which, again, another layer of asphalt about 1½in. thick is laid, and is finally painted over with pure asphaltum.

Asphalt, asphalt-concrete and concrete slabs are now being used for covering the floors of reservoirs, the joints being filled up with asphalt or cement motar respectively. To avoid cracks in concrete due to expansion and contraction, it would be an improvement if the joints were run with asphalt. York stone, brick and cobble stones are also used; but the first is expensive, and the two last are dirty. If strength is required with a minimum thickness, concrete slabs with expanded metal embedded in them, as at Cardiff and at Warrington, can be used. All rendering should be done before the concrete sets, or, if that is impossible, the surface should be roughed and washed before the coating is put on. The concrete commonly used in reservoir construction varies from 5 to 1 to 7 to 1, and should be made of clean materials, with a large percentage of small stuff and sand; and if crushed by machine the fine dust should always be retained. How to lay concrete is a subject which is frequently discussed. Personally I favour a rather (but not too) wet concrete, so as to obtain a mass which, when slightly rammed, moves like an ordinary table jelly and brings the liquid cement to the surface.

Puddle varies considerably in different localities; and where for a certain head 1ft. would be sufficient in one case, in another 2ft. would be required. The best puddle for waterworks construction is the bluish-grey clay common in the carboniferous formation of the mining districts. The worst kind I know is the Devonshire potters' clay, known as kaolin, it being the disintegrated felspar of granite rock; some of the yellow clays, however, are very good. To test clay for waterworks purposes, a piece of about 1in. diameter should be rolled to about 1ft. long; and if it will support itself without breaking when held by one end, it may be classed as good. The weight which can be put on good clay varies from 1½ to 4 tons per sq. ft. An admixture of cinders with puddle will stop rats from making passages through it. Puddle and concrete can be used together with advantage when the reservoir is constructed on a permeable formation or jointed rock; but when there is a probability of unequal settlement, it is advisable to use puddle with asphalt or bituminous sheeting laid on the top of bricks driven into the puddle, as this gives a considerable amount of elasticity

---

* A paper read before the annual general meeting of the British Association of Waterworks Engineers at Birkenhead, July, 1901.

The thickness of puddle generally varies between 9in. and 24in., according to the class of material and the head of water to be resisted; but when it is used for reservoir floors it ought to be well selected and placed *in situ* in thin layers, well worked by cutting, cross-cutting and ramming; dirty joints must be avoided, and if a little gravel is added to the puddle it will increase its weight-carrying capacity and prevent it shrinking or cracking so quickly. When there is a good natural bed of clay in the bottom of a reservoir, as in some of those in the Thames Valley, a thin layer of cement-concrete, or concrete slabs, will be sufficient to protect it and facilitate cleaning out. Good clay beds or solid rock make the best foundations, but the rock should be stepped if there is a considerable dip in the strata, and in clay beds the puddle core of the embankment should be sunk 2ft. to 4ft. into the natural clay.

Gravel and coarse sand make good foundations if kept from spreading, whereas silt and fine sand give much trouble, and, as a rule, require piling. If the bottom of the reservoir is founded on book-leaf clay, care must be taken to see that it is stable and not inclined to slide on its beds; this clay is very treacherous, and great care is required to make a successful job of the work founded upon it.

Reservoirs should never be constructed on made ground unless it has been thoroughly consolidated, and even then it may be advisable to increase the footings, or carry piers down to the orginal ground level, so as to act as bearing pillars.

Where the bottom of a reservoir is waterlogged, or of very absorbent material, and there is any difficulty in getting the concrete to set, the construction applied at the Charlottenberg reservoir of the Berlin waterworks can be adopted, bitumenised paper being spread over the bottom previous to the first layer of concrete being put in, as shown at F (Fig. 1).

There is a greater difficulty in dealing with the floors of covered reservoirs than with open ones, because the weight of the piers, walls and floor gives rise to unequal pressures on the foundations.

Where springs are met with the water should be led away from the site; or if, owing to the contour of the surrounding land, that is impossible, a valve may be placed in the bottom to allow the water, if pure, to enter the reservoir. Air gives trouble in some cases, as at the Devonport works, where Mr. Francis had much difficulty in completing the Belliver reservoir, but it can be dealt with in a similar manner to water.

An example of building a covered reservoir, holding 660,000 gallons, in bad ground at Bordeaux may be referred to here. The site was one which with the ordinary methods of construction would have required piling all over, the foundation being peat and black mud. This would have been very costly, so it was decided to erect an iron reservoir having sides 0·15in. thick and the bottom 0·20in. thick, supported on a grillage of 8in. girders, the only piles put in being immediately under the columns supporting the roof. Eighty tons of cast-iron and 320 tons of wrought iron were used in the construction, the cost being £7,800, or £11 16s. 4d. per 1,000 gallons.

Practice varies considerably in the designing of service reservoir walls, some being economical in design, while others are far from it. At the same time we must not be led to conclude that the heaviest wall necessarily shows an example of bad design, for there are cases where local conditions make it absolutely necessary to design heavy walls, and one design for all cases cannot be adhered to. Considering the large number of retaining walls that have been erected in connection with railways, gasworks and waterworks in this country, our knowledge of the lateral pressure to which such walls are subjected is very small indeed. The researches of and theories advanced by Coloumb, Barlow, Poncelot, Rankine, Levy, Boussinesq, together with the practical studies of Lieutenant Hope, General Pasley, General Cunningham, General Burgoyne, Colonel Michon and Sir Benjamin Baker, have done much to give us a wider knowledge of the subject; but a larger number of practical tests will have to be made before we can design walls on a thoroughly sound and economical basis.

The following experiments made by General Burgoyne are instructive, although they would have been of considerably more value if some kind of mortar had been used in the building of the walls. The material was distributed as shown in the four examples (Figs. 2, 3, 4 and 5), the walls all being 20ft. long and 20ft. in height and the mean thickness one-sixth of the height. In Fig. 2 the thickness was 5ft. 4in. at the base and 1ft. 4in. at the top, with a front batter of 1 in 5. In Fig. 4 the thickness was the same, but the batter was on the back instead of the front. In Figs. 3 and 5 the thickness was 3ft. 4in. throughout. The walls consisted of rough granite blocks laid dry, with a backing of loose earth, filled in at random during a very wet winter. The wall in Fig. 2 stood intact, but that in Fig. 3 tilted forward about 2in. at the top. Those shown in Figs. 4 and 5 both fell when the filling reached a height of 17ft. That in Fig. 4 broke at a height of 5ft. 6in. above the base, and after it had been pushed over some distance at the top. That shown in Fig. 5 was gradually pushed forward about 18in. bodily, and then broke off at about a quarter the height, in a manner similar to which the Barry Dock wall failed last summer. These walls, without mortar, stood about 50 per cent. more pressure than indicated by theory, and it is instructive to notice their relative stability, as each contained the same amount of material. The effect of varying the section of walls is clearly shown in the following examples,* where each wall has the same stability, under conditions which were common to each: Height of walls, 18ft.; top thickness, 2ft.; weight of each, 100lb. per cub. ft.; weight of masonry, 150lb. per cub. ft.; natural slope of earth, 34 degs.; and factor of safety, 3.

In each case the earth pressure is taken to be normal to the back of the wall; but should it be taken as inclined, the quantity of masonry will be less in each case. From these sections it will be seen that as the backward inclination of the rear face of wall increases, the quantity of material required for the same stability decreases, and the influence of front batter can be seen by comparing types A and B. If the walls were surcharged, a little extra thickness would be required.

Type.	Thickness of Base.	Cubic Yards per Lineal Foot of Wall.	Percentage of Material. Rectangular Wall = 100.
	9·4	3·80	73
	7·1	3·03	58
	5·4	2·47	47½
	3·4	1·8	35

Walls built of heavy material need not be quite as thick as those of lighter weight. The length of a wall also has a considerable influence on its strength, and it is advisable to construct long walls with a heavier section than short ones. Counterforts, no doubt, effect a slight saving in material, but the total cost of construction is about the same.

In deep reservoirs, or where the bottom is compressible, it is best to build the wall first, and thus obtain the advantage of shoring up the earth at the rear of the wall during construction. Unequal settlement, and consequent breaking of the concrete used for the floor of a reservoir, is also thereby avoided.

Brunel's and Stevenson's types of retaining walls are shown in Figs. 6 and 7, either of which will answer for reservoir purposes, although the latter is the better. There is always a risk of a wall which does not stand on a horizontal base being pushed back a little into the earth, thereby causing a tensile strain at the junction of floor and wall, and ultimately fracture and leakage. The thickness in Brunel's type is one-sixth of the height, with a curved face of 150ft. radius, batter of 1 in 5, and counterforts 2ft. 6in. wide at every 10ft. The thickness in Stevenson's type (for masonry) is one-third of the height at the base and one-fourth of the height half-way up the wall, with a curved face batter of 1 in 6.

Two examples of walls designed by me are shown in Figs. 8 and 9. The latter has a thickness of base one-third of the height, and would do very well in good earth; while in the former the thickness is four-elevenths of the height, and gives a rather heavier section, which might be adopted where the earth backing is not so good as in the first case.

The thickness and stability of the walls may

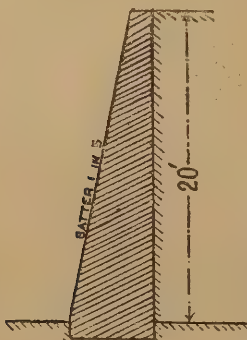

FIG. 2.

* Merriman on "Retaining Walls."

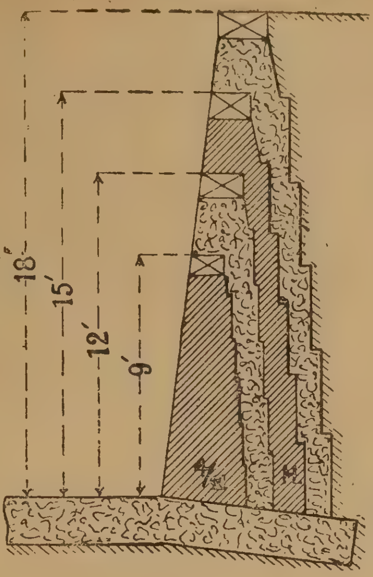

FIG. 8.

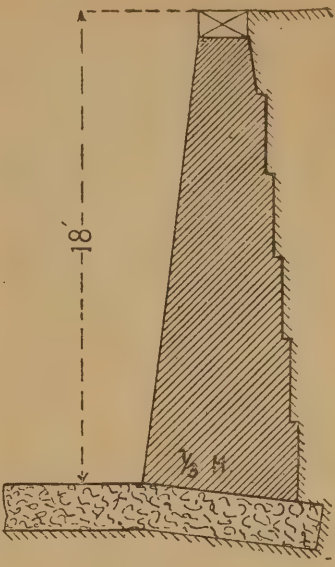

FIG. 9.

be calculated by means of Rankine's and other well-known formulæ, or by the graphic method given in Rivington's "Notes on Building Construction," Part IV. It has been pointed out by Sir Benjamin Baker that the usual formulæ for the lateral pressure of earth backing give a factor of safety of about 2.

As there is much to be learned from failures, a description of the case of the Hartley reservoir, Plymouth, will be instructive. This reservoir, when first built, had a wall of thin masonry backed with puddle; but as some time after it had been finished the walls were found to be gradually bulging forward, it was decided to place another thin wall and a layer of puddle in front of the original one. This, too, gave way in course of time, and it was finally decided to build a substantial and well-designed wall in front of the original one, after removing that shown by dotted lines in Fig. 10. The reservoir contains about 7,200,000 gals., and is now water-tight. The failure appears to have been due to the thinness of the wall, helped, perhaps, by the shrinking of the puddle during a dry season, and consequent swelling after heavy rains.

The covering of reservoirs is a matter upon which there is much difference of opinion amongst engineers and the medical profession. Whether there is any necessity for covering reservoirs depends upon the character of the water and the purity of the atmosphere in the neighbourhood of the reservoir. Generally speaking, it will be found necessary to cover all reservoirs wherein hard waters are stored, but in some instances only where soft waters are stored. In the neighbourhood of large manufacturing districts it may be necessary to cover them whether the water be hard or soft. It appears to be common-sense that if water is polluted by the atmosphere, or the action of sunlight causes vegetable matter to grow in abundance, the reservoir should be covered.

Dr. Procucci, speaking of the bacterial effect of sunlight, states that there is a marked decrease of bacteria in sunlight and an increase in the dark. Dr. Samuel Rideal also, in his book on "Water, and its Purification," says: "The improvement of water in reservoirs is largely due to the deposition of suspended mineral matter and bacteria; but, in addition, open storage reservoirs favour the beneficial action of aëration and light."

In deciding the kind of roof to adopt, consideration must be given to the durability and weight of the material it is intended to use. The life of ironwork has been placed by Sir R. Rawlinson at fifty years. If, however, the roof be properly designed, there is no reason why its durability should be less than any other kind of structure, provided that the ironwork be embedded in concrete.

Groined brick arches make a good and durable covering, but concrete is much cheaper to construct, and is lighter per sq. ft. of covering, owing to the reduction in the quantity of material required. A light and strong concrete roof can be obtained with a span of 12ft., rise of 2ft. 6in., and thickness at crown of 6in.; or if granolithic concrete be used, the weight can be somewhat reduced. Groined elliptical arches require a small amount of material, and give clear headroom in each direction, which facilitates ventilation. Semicircular arches are expensive, owing to the loss of space, as the water-level should never be higher than about 3in. below the line of springing. There are, however, exceptions, as in the case of the Bath reservoir.

Amongst the many ways of covering reservoirs the following may be mentioned, though Nos. 1 and 5 cannot be recommended:—

(1) Wood roof with slates;
(2) Concrete arches;
(3) Girders and jack arches;
(4) Girders and concrete slabs;
(5) Corrugated iron;
(6) Concrete enclosing girders and joists;
(7) Expanded metal and concrete.

The roof should be well ventilated, and have inspection manholes fixed in suitable positions, so that direct light may never be admitted except when cleaning out the reservoir. For this purpose a manhole-cover 15in. by 15in. to every 300 sq. ft. of roof is sufficient. If the roof is carried from the side walls, which in covered reservoirs are usually built with vertical faces so as to reduce the roof area, they must be designed accordingly bearing in mind the fact that any outward pressure resists the overturning effect of the earth backing. In America it is a common practice to take the outward pressure of the roof upon a metallic ring fixed near and around the top of the wall. If the roof rises above the surrounding ground level, the effect of the wind-pressure transferred to the walls must also be borne in mind. Occasionally, to avoid the turning movement on the wall, the roof is supported from a point some distance behind the side walls. This method can be adopted when it is found necessary to cover an existing open reservoir. When the roof is entirely underground, it is usual to cover it with 12in. to 24in. of earth.

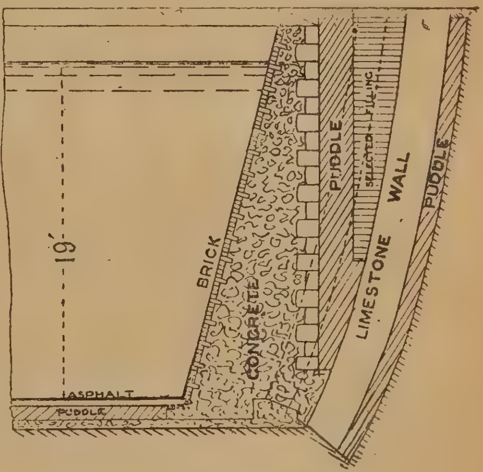

FIG. 10.

To prevent rainwater entering the reservoir, it is necessary to cover the roof with some impervious material, such as concrete, puddle, asphalt or bitumen sheeting, the last being the cheapest and lightest. All spandrels should be drained away from the reservoir.

The whole weight of the roof is seldom carried by the walls, excepting in small reservoirs, some portion being, as a rule, carried on concrete or brick piers, or on steel or iron columns. The piers must be designed according to the weight they have to carry and their length. It is cheaper, owing to their small section, to build piers of brick than of concrete, and from one-fifth to one-sixth of the height is the usual width for the side of a square pier. To distribute the pressure over a greater area of footings with the same quantity of material in the piers, a cruciform section is sometimes adopted. Pier footings should never penetrate through the full thickness of the floor, or they will form lines of weakness and leakage; and where there is trouble from upward pressure inverted arches should be built at the bottom of the reservoir, and the pressure transmitted through the piers or columns to the roof, which can be weighted accordingly.

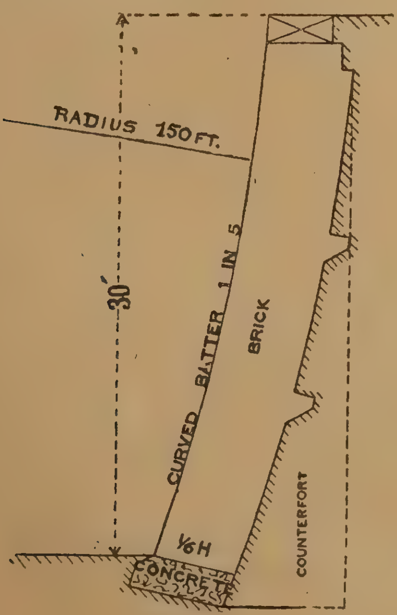

FIG. 6.

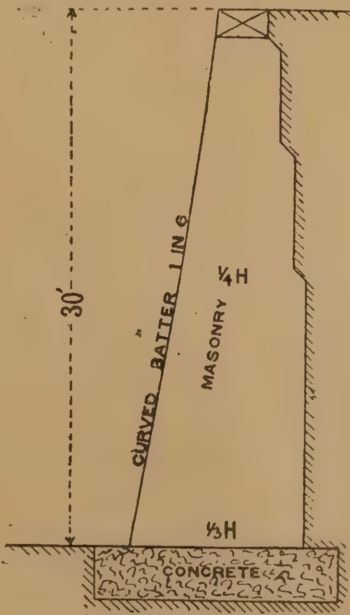

FIG. 7.

The cost of executing the work in different portions of service reservoirs may be apportioned as follows :—

For Open Reservoirs.	For Covered Reservoirs.
Excavation, 15 per cent. of total cost.	Excavation, 10 per cent. of total cost.
Floors, 35 per cent. of total cost.	Floors, 24 per cent. of total cost.
Walls, 50 per cent. of total cost.	Walls, 28 per cent. of total cost,
	Roof, 38 per cent. of total cost.

Small reservoirs are more expensive to construct per 1,000 gals. of capacity than large ones. With regard to the question of rectangular as compared with circular reservoirs, I think that engineers are not fully alive to the advantages to be gained by making reservoirs circular in plan. As to wall length, in a reservoir having an area of 10,000 sq. ft., if square, 100ft. by 100ft., the wall length will be 400ft.; if rectangular, 80ft. by 125ft., 410ft.; and if circular, and approximately 113ft. in diameter, 355ft. There is thus an average difference of 50ft. between the length of the circular walls and the straight ones, and the narrower the rectangular reservoir is the greater will be the difference.

The cost of a properly-designed open reservoir to hold 12ft. depth of water may be anything between £3 and £5 per ft. run of wall, and taking a mean cost of £4 with the above lengths the relative costs will be, if square, £1,600; if rectangular, £1,640; and if circular, £1,420: representing a saving of about 12½ per cent, or 5s. 4d. per 1,000 gallons, on a comparatively small reservoir of 750,000 gallons capacity.

Besides this, in circular reservoirs the walls need not be designed as thick as in rectangular ones, and there will consequently be a large saving in cost. The thickness of straight walls for rectangular service reservoirs varies between a quarter and two-fifths of the depth, while those of circular reservoirs or gasholder tanks have been found strong enough where the thickness has been between the limits of one-sixth and one-tenth of the depth.

After careful consideration it must be concluded that circular reservoirs are from 20 to 40 per cent. cheaper than rectangular ones, although it must be borne in mind that the former are not so economical in ground space as the latter.

Perhaps the finest example in the world of a service reservoir is that at Buenos Ayres,* which has a capacity of

* Proceedings, Institution of Civil Engineers, vol. cxxiv.

16,000,000 gals., and is built in the French Renaissance style with elaborate enrichments. There are three tiers of tanks, each tier being divided into four compartments, 135ft sq. and 13ft. deep, each tank containing about 1,324,000. gals. Each tank is supported upon cast-iron columns, connected together with plate girders. The range of temperature is about 70 degs. F., and the arrangements for dealing with expansion are very neat. In Paris there are several reservoirs of this class, that at Montmartre being, perhaps, the best example. A large number of examples of service reservoirs will also be found in a paper by Mr. W. Morris on "Covered Service Reservoirs," in the Proceedings of the Institution of Civil Engineers, vol. lxxiii.

Masters and Men.

The Management of the Penrhyn Quarries state that they have no difficulty in meeting orders, and the steamer service from Port Penrhyn is regularly maintained.

The Four Cardiff Branches of Builders' Labourers in connection with the Navvies and General Labourers' Union have given notice to the masters for an advance of wages of one penny per hour, to come into force on May 1st.

The Master-Builders of Gloucester have given notice to the different trades for an alteration in the time of starting work in the winter and to change the time from June to December for the expiration of notices for any proposed alterations in the working rules in future.

Perth Plasterers' Strike.—In connection with the Perth plasterers' strike, which at present prevails as to the reduction of ½d. per hour on the men's wages, an important development has taken place. Mr. Peebles, secretary of the Perth Masters' Association, recently received a note from the secretary of the Glasgow Labour Bureau stating that he noticed the masters were having trouble with their workmen in Perth at present, and that he could supply the men required to do the work. The Perth secretary wrote a reply to this letter, and at present the masters are hopeful of the places of those on strike being filled.

A Lock-Out at Maidstone.—The largest firm in Maidstone locked its men out last week because they arrived at 8.30 instead of 8 a.m., the time fixed by the Master-Builders' Association. Other firms followed their action, and the Masters' Association has resolved that there shall be a general lock-out of carpenters, joiners and bricklayers. The men had expressed their willingness to begin work during the present month at 7.30 if they were allowed from 8.30 till 9 o'clock for breakfast, but the masters would not agree to this. The dispute affects several hundred bricklayers and carpenters belonging to trades-unions.

The Glasgow Exhibition Plumbing Dispute.—Sheriff Balfour, the arbitrator between the Master and Operative Plumbers' Associations in Glasgow, has given his award with reference to a dispute which arose out of the Glasgow Exhibition work regarding the question of payment of operative plumbers for work done by night-shift. The dispute arose as follows:—Certain operatives were employed by Mr. Renfrew, the plumber, at the Glasgow Exhibition, and in consequence of the requirements of the Exhibition they were unable to work during the day and so worked during the night. They were paid on the footing of receiving the usual wages for fifty-one hours per week and time-and-half for the time wrought after the fifty-one hours, and offered 1s. per night extra. They received the payment under protest, and claimed to be paid time-and-half for all night-work, without reference to working fifty-one hours in the week. Nothing was said in the rules as to night-shifts except as to payment over fifty-one hours. The arbitrator considers the payment made fair and reasonable, and that the men are not entitled to time-and-half for the whole of the night-work.

Labour in the Colonies.—The January circulars of the Emigrants' Information Office, 31, Broadway, Westminster, S.W., and the annual editions of the penny handbooks, show the present prospects of emigration. A new handbook on the West African Colonies has just been issued. It is too early in the year for the ordinary emigrant to emigrate to Canada in search of employment. The report for 1900, recently issued under the Factories Act, shows that the numbers of factories and employees in New South Wales comprised within the Act both increased, and that trades were generally prosperous. Improvement was shown in the building trade. In Sydney wages in many trades, as the building trade, have risen, but wage-earners complain that the cost of living is rising in greater proportion owing to the proposed new Federal Tariff. The building trade is now less active than it was, but all other trades continue to be fairly well employed, and there is still some opening for general mechanics, plumbers, joiners, carpenters and good labourers. In Victoria there is no general demand for more labour, but a competent mechanic has not much difficulty in finding work. The Boards appointed under the Factories Act have fixed the lowest wages to be paid to labourers in the pottery trade at 40s. per week of forty-eight hours, and to females over twenty years of age employed in the making of tiles at 17s. 6d. per week of forty-eight hours. The annual report of the Inspector of Factories for 1900 states that the numbers of employees and of factories were both larger than in any previous year, showing that there had been a steady improvement in trade. In South Australia there is practically no demand for more mechanics in the towns, but a skilled hand, such as a mason, bricklayer, engine fitter, blacksmith, joiner or carpenter, can generally find employment after looking about for a little. In Queensland, owing mainly to the scarcity of employment caused by the long drought, the general supply of labour is in excess of the demand. The report of the Government Labour Bureau in Western Australia for the quarter ending 30th September last shows as follows: There is a demand for men in the building and other trades at Northam, York, and two or three other places, but the supply of men is sufficient at Perth, Fremantle, Albany and all other towns; while at Coolgardie, Kalgoorlie, Boulder and Collie the supply is in some cases actually greater than the demand. In New Zealand the building trades have been busy almost everywhere (but not at Wellington or Dunedin), and at Invercargill bricklayers have been in demand. The engineering trade is not giving full employment to men at Dunedin and Wellington; but elsewhere it is fairly good, and in Auckland blacksmithing and boilermaking have been brisk. No one is now allowed to land in South Africa without a permit. This must be applied for at the Permit Office, 39, Victoria Street, London, S.W. The applicant must possess £100, or prove that he is in a position to maintain himself in South Africa. Applicants living within fifty miles of London must apply in person. These permits are no guarantee that the holders will be allowed to proceed inland. Only refugees, Government employees and persons engaged in a service of a public nature will be permitted to proceed to the Transvaal.

The Article on Albi Cathedral which appeared in our issue for December 18th last was written by Mr. Hubert C. Corlette, A.R.I.B.A., and formed part of his article in The Architectural Review for November, 1900; to which issue we would refer those readers who desire additional particulars and further illustrations of this interesting building.

The New Patent Office Library was opened to the public last Thursday. The building occupies the site of the old premises facing Southampton Buildings, off Chancery Lane, and has a frontage of 130ft. It is built of ivory-white bricks and Portland stone. The library itself is 140ft. long, 59ft. 6in. wide and 75ft. high. Around the sides run two galleries, carried by rows of ornamental cast-iron columns with Corinthian capitals. The galleries running the length of the library on either side are 19ft. wide, whilst those at the ends, which have no other purpose than to connect the sides, are 6ft. wide. Two cast-iron staircases, one at each end of the hall, lead to the galleries. Under the present arrangements the public will only be admitted to the ground floor and the first gallery. The second gallery will be only accessible to the staff. The cost of the new buildings has been about £160,000.

New Patents.

These patents are open to opposition until February 18th.

1901.—Sewage Treatment.—517. F. Candy, 56. Nightingale Lane, Balham, London, S.W. One part of this invention relates to the addition of residue ("burnt-out ash") to the sewage, which is then passed on to bacteria beds. The rest of the invention concerns improvements in automatic apparatus for effecting intermittent or periodical discharge of liquid stored in a tank or conduit. Float-actuated mechanism is combined with a discharge valve and tipping vessel, so that the discharge of the latter is simultaneous with the closing of the valve when the liquid has descended to a predetermined level.

Portland Cement.—2,409. H. E. Ziisager, 70, H.C. Oerstedsvej, Frederiksberg, Copenhagen. One (or all) of the raw materials is reduced in its natural moist state, without drying. The materials are then ground and mixed in tube-mills, with the addition of the least possible quantity of water; and the thick sludge so obtained is burnt in rotary kilns, and afterwards ground. This process is claimed to be more trustworthy, simpler and cheaper than those in vogue.

Floor Cramps.—3,106. T. Potter, 5, Outram Road, Croydon. This cramp is intended for use with boards nailed direct to concrete, or where the spaces between ordinary joists are filled up flush, or where "counter-flooring" is employed—in which cases the ordinary cramp cannot be used. This cramp therefore consists of a lever arm which is pivoted by a pin passed through a length of timber which is laid just above the boards, with one end against a wall or other support. The lever has an automatic strut or stay to hold it in position.

Pipe Joints under Pressure.—18,017. C. Radcliffe, 23, Dumfries Place, and D. Pugh, 209, Carlisle Street; both of Cardiff. Over the joint a pair of cone-backed flanges are adapted to be forced together longitudinally by a clamp which is in two halves drawn together laterally.

The following specifications were published on Saturday last, and are open to opposition until February 24th. The names in italics are those of the communicators of the inventions. A summary of the more important of them will be given next week.

1900.—23,198, McPhail, treatment of sewage &c. 23,435, Key, ventilation of buildings. 23,827, Robertson & Robertson, machines for bending pipes and other articles.

1901.—457, Brookes (*Hörisch*), hardening artificial stone. 961, Wilson street and other gas lamps. 1,096, Webb, lamp heads particularly adapted to lamps for the extraction and destruction of sewer gas. 1,401, Stevens, Major, Stevens & Stevens, controlling arrangements for electric lifts. 1,588, Thompson drain-pipes or conduits. 2,500, Jenkins portable buildings. 2,617, Eadie & Tannahill, pipe joints. 3,014, Waine, locks and latches. 3,029, Cliff & Reynolds, lavatory basins, baths, &c. 3,539, Fryer & McKeggie, windows. 3,620, Melsom, paving blocks for tramways. 3,768, Michaelis, hydraulic cement. 3,811 Tomlinson & Tomlinson, reversible sash windows. 5,782, Rothwell & Rothwell, device for displaying and contrasting designs or tints for mural decorations. 9,523, Kosiol & Randall, sink overflows and wastes. 13,773, Douglas, Venetian blinds. 16,732, Whitehead, sash-fasteners. 17,570, Reavis, fireproof structures. 18,156, Morgan, apparatus for hoisting and conveying. 19,087, Schmidt, ventilating offices. 19,126, Gay, automatic saw guide. 20,122, Viewig, hinges. 21,441, Cutler, means for locking stop-cocks. 22,048, Lake (*Frazzi*), floors, ceilings, &c. 22,827, Anderson, combined hollow brick and tile-facing for walls. 22,830, Anderson, combined ventilated and drained brick-tile paving blocks for streets, &c. 22,981, Rossmann, resilient plates for building purposes. 23,402, Campbell, sinks.

The Rebuilding of London that is now in progress is characterised by Mr. Max Beerbohm as "ruthless ruin."

Keystones.

Mr. William Groom, of Aylesbury, who carried on the business of a builder at Leighton Buzzard for many years, died recently at the age of seventy-eight years.

The Affairs of Mr. L. F. Shove, architect, of Bristol, were considered at an adjourned meeting of creditors held last week at the Official Receiver's office.

A New Hospital at Sutton has been erected in Hill Road. Mr. Passmore Edwards has borne the cost of the building, and Mr. Ralph C. Forster has given the site. Mr. Cecil A. Sharp was the architect, and Mr. J. B. Potter the builder, both of Sutton. It provides accommodation for twelve patients.

Partnership Dissolved.—Since January 1st last, the partnership between Messrs. Dalgleish & Dickens-Lewis, architects, of Talbot Chambers, Shrewsbury, has been dissolved, and they now practise separately at the following addresses: Mr. C. R. Dalgleish, Central Chambers, Wellington, and 18, Talbot Chambers, Shrewsbury; and Mr. G. Dickens-Lewis, 12A, Talbot Chambers, Shrewsbury.

Specifications for Fire-Resisting Buildings.—The Associated Fire Offices have drawn up two specifications for cotton mills, woollen mills, warehouses and similar buildings with the object of encouraging better fire-resisting construction. Owing to the great pressure on our space this week we are unable to print these specifications; but we hope to do so in our next issue.

Birmingham University Buildings.—In the course of the speech which he delivered last Wednesday at the annual Court of Governors of the Birmingham University, Mr. Chamberlain said that the buildings of this new university could be erected and equipped for less than £1,000,000. They had £300,000 in hand, and accordingly out of ten working blocks, of which the complete university would ultimately consist, they proposed to begin with the erection of three, and these three blocks would give them the schools of mining, metallurgy, of civil, mechanical and electrical engineering, together with the great hall of the University. Messrs. Aston Webb and Ingress Bell are the architects. Lord Calthorpe has given the site.

Decorative Art.—The Lord Lieutenant of Ireland, Earl Cadogan, in opening in Dublin last week a convention and decorative exhibition in connection with the Association of Master-Painters in Ireland, said it was a subject of sincere congratulation that the close of the nineteenth century, the beginning of which was so unsatisfactory in its influence on art as applied to decoration, should have seen the cradling of such an institution as that in connection with which they were met. He thought that outside Italy there were few towns which could show in their buildings such excellent models of the decorative art as could be found in Dublin, and he hoped that their exhibition would have its effect in the encouragement of the beautiful in buildings and in their decoration.

The Manchester Society of Architects held a meeting last Thursday, Mr. A. Darbyshire, president, in the chair. Mr. Hugh Stannus, F.R.I.BA., having been elected a Fellow of the Society, and Mr. Thomas B. Daniel an Associate, the president announced that the monthly prize for the best design for a shop-front in the competition in connection with the junior classes for design had been awarded to Mr. Claude Paterson, of Bowdon; the November subject for a band-stand was won by Mr. H. Solomon. Mr. J. D. Crace, Hon. A.R.I.B.A., then read a paper on "The Relation of Colour to Architecture," in which he emphasized the necessity of the decorator sympathizing with the object of the architect, and using his art as the handmaid of architecture, taking care that his scheme of colour design should be such as not to lead the interest to stray from the lines which expressed the structure of the building. The leading values of colour should assist in expressing the stability of the building, for directly the structure was injured the sense of repose was disturbed.

Blackpool Cemetery Competition.—Messrs. Runton & Barry, A.R.I.B.A., of Savile Chambers, Savile Street, Hull, have been awarded the first premium in this competition.

"The Past, Present and Future of British Architecture."—This, the presidential address delivered by Mr. Frank Caws, F.R.I.B.A., before the Northern Architectural Association last November (reported in our issue for November 20th), has been reprinted in pamphlet form.

Mr. Edward Sale, architect and surveyor, of Eccleston, died at his residence, Higham House, on December 27th. Deceased carried out extensive alterations at Wrightington Hall in 1860. He was retained by Mr. Thomas C. Dicconson, and finally became his agent. After some years he resumed his profession, and in 1870 he was appointed to the district surveyorship of the Leyland Hundred Highway Board.

Municipal Buildings for Hampstead. — The Hampstead Borough Council is contemplating the erection of a block of new municipal buildings, the accommodation at the Town Hall, which was erected in 1877, being now wholly insufficient. The works committee will recommend the Council to purchase a piece of land, one acre in extent, at the corner of Finchley and Lymington Roads, at a cost of £8,000 for the site.

Mr. Alfred Gilbert, R.A., has announced the subjects for his series of addresses on sculpture at the Royal Academy, the first of which will be delivered on Monday, February 17th. The quaintly-arranged titles to his six lectures read as if they were broken parts of a complete sentence; they are: (1) "Endeavour," (2) "To Accomplish," (3) "Creation," (4) "Revise and Use," (5) "Experience," (6) "To a Proper End."

Mr. John Brett, A.R.A., died last week at the age of seventy years. Mr. Brett is especially known for his studies of sea and rocks. In early life he came strongly under the influence of the Pre-Raphaelite movement. In 1859 he showed his famous "Val d'Aosta," in which he endeavoured, not without success, to carry out the principles of the Pre-Raphaelites in landscape-painting. Very few artists have tried to do this, though Holman Hunt, in addition to Brett, showed that the aims of the school could be illustrated by landscape as well as by romantic figure pictures.

The T-Square Club.—Mr. C. W. Stephenson presided at the third smoking concert of this season, which was held in the foyer of Covent Garden Theatre on Wednesday evening last. The programme was as usual excellent, and the attendance up to the average. Songs were given by Mr. James Davis, musical sketches by Mr. Ulp Smith, humorous stories by Mr. C. W. Wreford, and burlesque imitations by Mr. Arthur Helmore. The card-tricks of Mr. Fred Moore were particularly clever. The chief attraction was, however, the singing of the Maori Princess Te Rangi Pai, a new mezzo-soprano. The Committee have decided that the club concert on February 5th shall also be a "smoker," the date of the "ladies night" having been changed to March 5th.

Early Irish Architecture.—At a meeting of the Architectural Association of Ireland last week, Mr. A. Scott presiding, Mr. P. J. Lynch of Limerick, read a paper on the "Early Christian Architecture of Ireland." He claimed the style of ornamental architecture in Ireland to be anterior to the Norman Invasion, which was advanced by Petrie, yet not completely proved; but recent research on the Continent and amongst pre-Norman remains in Great Britain goes far to remove all doubts. The resemblance between Irish round towers and the Continental church towers at Ravenna, illustrated by views of both, was clearly demonstrated, and the likeness between Lombardic and Irish architecture pointed out. The direct influence of the Lombard or Comacine masters on this early architecture had yet to be proved, though in later years it was evident from the memorial slab of the master in Christ Church Cathedral a strong plea was advanced for enquiry as to whether any portions of Cormac's Chapel, Cashel, might not be tenth century, as was generally supposed, until Petrie advanced it to the twelfth century, Petrie admitting at the same time that the records might mean a restoration.

The Kursaal at Harrogate is now being erected, the memorial stone having just been laid.

The Glasgow Technical College Architectural Craftsmen's Society held a meeting last Friday. Professor Gourlay, B.Sc., A.R.I.B.A., occupied the chair. Mr. A. B. McDonald, M.Inst.C.E., civil engineer, lectured on "The Highlands of Central Europe," describing a trip down the Rhine valley through Switzerland and the Tyrol.

Dr. G. B. Longstaff has consented to fill the office of president of the National Society for Checking the Abuses of Public Advertising, rendered vacant by the retirement of Mr. Alfred Waterhouse, R.A. It is interesting to note that several large towns (including Birmingham and York) are applying for powers of control of the same nature as those which are already in force for Edinburgh and Dover.

Sheffield Society of Architects and Surveyors.—At the meeting of this Society held last Thursday (Mr. P. Marshall in the chair) it was announced that the prizes for the best sets of measured drawings of buildings in the district had been awarded as follows: 1st prize, Mr. G. R Morris; 2nd prize, Mr. D. B. Jenkinson. Mr. William Watts, F.G.S., M.I.M.E., then read his paper on "The Uses of Mortar and Concrete," printed in this issue.

A Drill Hall for the Lhanbryd Volunteer Company of the 3rd V.B. Seaforth Highlanders has been erected and fitted up at a cost of about £600. The hall proper is 60ft. long and 25ft. wide, with an open roof to the apex and showing the roof principals. It will comfortably seat about 350 persons. The contractors were:—Masons, Messrs. Davidson & Hay; carpenter, Mr. James Cameron; plasterer, Mr. Alexander M'Iver; slater, Mr. James Wilson: plumbers, Messrs. Mackenzie & Russell; painter, Mr. Alexander Forsyth.

Unlighted and Unprotected Hoardings.—In the Thames Police Court recently a builder named Abraham Davis, of 19, Aldgate, was summoned for not keeping a hoarding and fence erected by him in Christian Street, St. George's, well-lighted during the night; further, with failing to put up a platform and handrail as a footway for passengers outside the hoarding and fence. Mr. George Hay Young prosecuted on behalf of the Stepney Borough Council. Defendant was fined £5 and 44s. costs on the first summons, and £5 and 23s. on the second.

New Companies.

Oakthorpe Sanitary Pipe Co., Ltd.

Registered to acquire the business carried on by Massey & Sons at Oakthorpe, Leicestershire; and to carry on the business of manufacturers of and dealers in sanitary pipes and other earthenware, &c. Capital £5,000 in £1 shares. The first directors are H. Southerd and J. Southerd. Registered office: The Pipe Works, Oakthorpe, Leicestershire.

IMPROVED COPING TILE

(PATENTED)

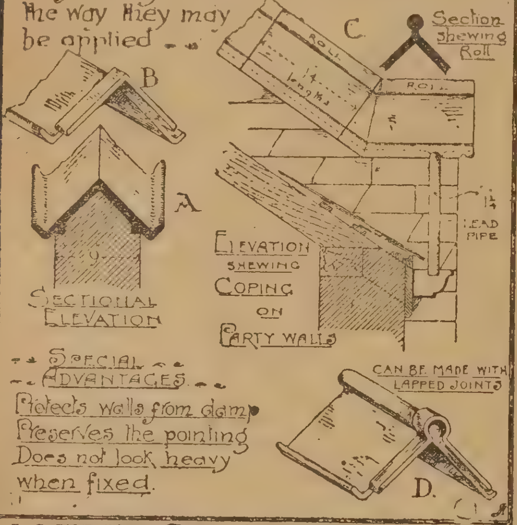
For GABLES, PARTY WALLS, &c.

WILLIAMS'S PATENT COPING TILES

INVENTED BY W. A. WILLIAMS A.R.I.B.A.

The attention of Architects, Surveyors, Builders and others is specially called to these Patent Coping Tiles [which have many advantages over ordinary coping] for Gables, Party-walls, fruit walls etc.

The following sketches shew these Tiles and the way they may be applied



B
C.
Section shewing Roll
ROLL
A
LEAD PIPE
ELEVATION SHEWING COPING ON PARTY WALLS
SECTIONAL ELEVATION
CAN BE MADE WITH LAPPED JOINTS
D.

SPECIAL ADVANTAGES

Protects walls from damp

Preserves the pointing

Does not look heavy when fixed.

J. C. EDWARDS TERRA-COTTA WORKS RUABON

This Coping prevents the water collected by it from running down and soaking into the wall beneath.

The end tile is provided with outlets, from which the water can be conducted to the eaves gutter or elsewhere by a small lead pipe, or the outlet holes can be omitted, the tile throated and set to let the water shoot clear of the building, but the pipe is recommended and the expense is trifling.

It can be used as well on the flat, as raking, for with a little care it can always be laid to a slight fall, the outlets then should not be more than 10 feet apart.

The Tiles are set and jointed in cement, the edges being scratched up rough to form a key, making a permanent and water-tight joint.

It will be seen that with these Copings the walls are protected from dampness, pointing preserved, rooms in roof kept dry, and defective flashings and fillets do not cause so much leakage. No other ordinary Coping answers the same purpose.

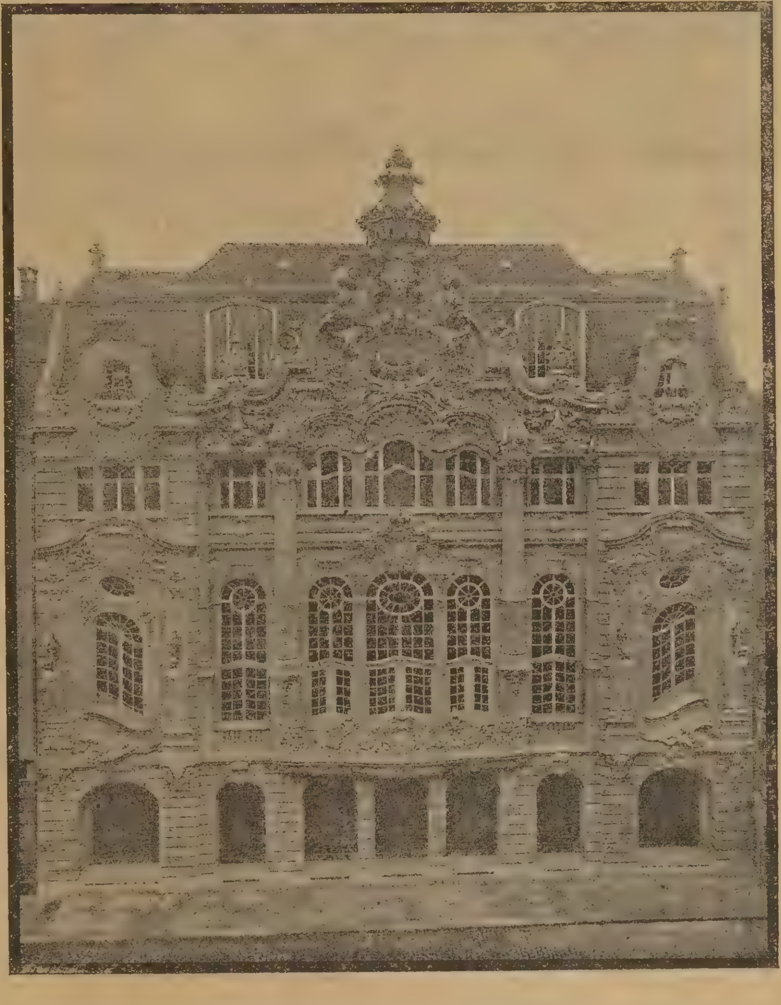
An Architectural Causerie.

Archæology and Architecture. ONE can hardly find two studies so closely allied to and dependent on one another as archæology and architecture, the first being too often neglected by the architect as being outside his scope, and the second very often monopolised by the archæologist, who, instead of co-working with an architect as such, puts his walls and excavations into the category of his own following. The classical learning implied by the term "archæology" is only a supplement to the science of architecture, and the only dividing line between the two would seem to be, that on the various objects of antiquity found within the buildings the architect can have no claim; and the archæologist's knowledge of such objects will serve him little in getting at the facts to be learned from excavated sites, where the plan of a former building is often all there is to be traced. We too often hear that such and such a point in connection with a mediæval building, even, is a question for the archæologist, when in reality it should have been an architect's business and delight to deal with. In all questions as to the development of planning lies the architect's province; and if on occasion he has to call in an archæologist to settle some abstruse point, that is no reason for his handing over the whole study to him. The archæologist's vocation is such a fascinating one that it would be hardly diminishing it were architecture to involve some of the points. Thus, architectural students study and draw the Parthenon with exactitude (more or less) from plates and diagrams—that is, they treat it as a piece of architecture—the highest example of architecture. But that done, it is forgotten by them, and to-day the Parthenon would only seem to be the affair of the archæological world. It is no longer a building, but a breath from the past; a sacred remnant to the archæologist—but what to the architect? What should it not be? One hears stories of the effect produced on sculptors on seeing the Hermes of Praxiteles at Olympia for the first time. They immediately go home and start an *Apollo* or something. Has the Parthenon ever inspired an architect in the same manner? Without declaring ourselves, we would say that it is rather as an archæologist that the architect visits the Acropolis and commences to note the entasis of the columns and the thousand other "optical refinements" that are in his note-book at home; and if seen in any modern building they are in almost every instance exaggerated — otherwise the "refinements" would not be seen. Surely the archæologist has enough without claiming the very *buildings* of antiquity! What with his coins, his gems, terracottas, bronzes, heads, torsos and fragments, his vases which occupy so great a portion of his time in placing together the thousand pieces thereof—with all these objects requiring so much of his care and delicate handling, it is perhaps not surprising that the archæologist should take supreme interest in the *chef d'œuvre* of the people of his studies and research; but he might remember that such an item as the Parthenon is strictly the architect's and should be looked on by him in the same way that an architect would and does regard, say, a Mycenæan pot from Crete or a coin dug up from some excavations on Classical soil. Crete affords an instance very much to the point. The result of Mr. Evans's continued probings into so-called Mycenæan and pre-Mycenæan ages have revealed stone staircases among the Palace at Knossos—a fact far more interesting and vital to the architect than to any body of archæologists. It is curious that, in Gothic architecture, there is not the same archæological monopoly of our cathedrals and abbeys, even when in a ruined state; and mediæval archæology does, on the whole, seem to work more hand in hand with architecture than classical archæology does. In fact, to take an extreme case far back beyond mediæval times, Stonehenge has received more attention in an architectural sense—that is, discussing it as architecture—than has the Parthenon in its present condition. Architectural societies have not been at all concerned about the recent restoration of the Parthenon, one of the most influential buildings on architecture for all ages. But Stonehenge, which could very safely be left to archæologists to deal with, has concerned them greatly. Of course Stonehenge is at home and Athens far away; and whereas we continually get foreign telegrams in the press concerning political affairs there, it is very rare that one hears of the work of the various "Foreign Schools" at Athens. Where archæological and architectural societies could work together would be in the publication of pamphlets giving a little more light on the various works being done on different soils, in addition to their regular "Journals," which only find their way to the specialist or very keen enthusiast and not to the members of the architectural world generally, who only require more data given them to take more interest in buildings which really belong to them and not to the archæologist. These pamphlets should give references to our museums in lieu of photographic illustrations—tending by this to make the galleries at Bloomsbury or South Kensington much more largely used *for what they contain* and not for idly passing an odd hour or so in a promenading panoramic review.

M**. J.



MODERN GERMAN ARCHITECTURE!
CENTRAL THEATRE, DRESDEN. LOSSOW AND VICHWEGER, ARCHITECTS.

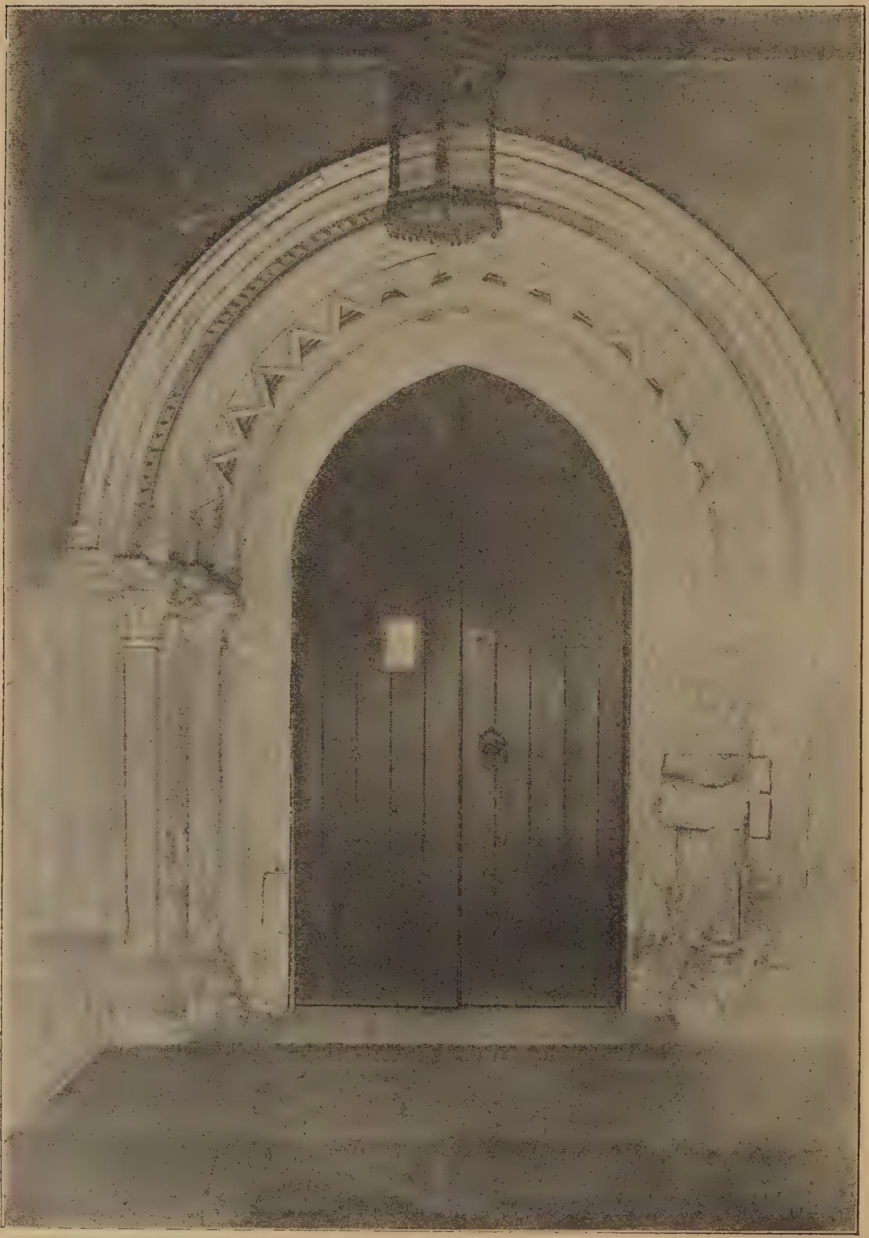
Hysterical Architecture. THERE is scarcely any need to say that we do not publish the illustration of the new Central Theatre at Dresden as a specimen of fine architecture, but rather to show what Continental architects are capable of perpetrating under the name of "Secessionism"; and though it would be totally unfair to brand all German architects with so writhing a taste, the fact should not be forgotten that this building is no mere doll's house, but a theatre of considerable size, which makes the selection all the more astonishing. The architects have tried to express the functions of the interior with a vengeance—especially in the stair windows—but their efforts are so wild and so utterly dominated by originality-at-all-cost that, instead of architecture, they have produced a wedding-cake in stone.

A I

THE TRANSITIONAL DOOR AT ORPINGTON CHURCH, KENT.

BY J. RUSSELL LARKBY.

ALTHOUGH by no means a period of architecture to be studied as a model for modern workmen, the Transitional detail as exhibited in some of our ancient churches is interesting and valuable as showing the approach to a form of art with which every architectural student makes himself conversant. The Transitional period is often spoken of as a style; but if one makes even a superficial enquiry it will at once be seen that the architecture of the latter part of the twelfth century cannot in any way be called a "style"; almost every feature of architecture was at that time undergoing a slow but complete change. There are, of course, features found in Transitional work—and beautiful features—not seen in earlier or later times, but this is the outcome of the fact that the late twelfth-century artist took what was good of the Norman style and blended it, after his fashion, with the developing beauty of the embryo Early English art. So, then, one may say that the insular features of Transitional architecture merely represent the merging of one style of art into another, rather than the creation of an altogether new school of thought. But if one is inclined to decry the copying of Transitional work, it must not be forgotten that the latter part of the twelfth century was an important period for English architecture, and should be placed on a much higher plane than the period of transition from Early English to Decorated work. It should not be forgotten that not only the minor details were changed during the years 1160-85, but also that the change affected even the plan appearance of buildings. A comparison readily suggests itself between the solid Norman nave of Durham and the chaste beauty of the nave at Wells. Both have individual character marking the work of two different periods, and a connecting link can be pointed to in the Transitional Galilee of Durham, which contains some of the heaviness of the one blended with a shadow of the beauty in the other.



WEST DOOR, ORPINGTON CHURCH, KENT.

Attention may now be drawn to the simple example illustrated by the accompanying sketches, which, it is hoped, will show to a small extent the bold Norman work passing under the softening influence of Early English art.

It is not difficult to place one's hand on certain details and pronounce them to be purely Norman or purely Early English, so well is the Transitional period in evidence. Thus, as evidence of the Norman style, we have (1) the recessed character of the mouldings, as shown by the dotted lines in the section (Fig. 1); (2) the bold chevron with the points resting on the inner pear-shaped mouldings; (3) the square abaci of the shafts; (4) the bases of the same, especially those of the north jamb, which, although much decayed, seem to consist of two plain squares simply chamfered off at the edges and angles.

As evidence of the Early English art, we have—

(1) The deep and excellent workings of the mouldings, two of which are pear-shaped.

(2) The use of dog-tooth ornament.

(3) The foliage, especially that of the northern capitals, which shows an approach to pure stiff-leaved work. The carving is perhaps roughly executed, but at the same time has considerable grace and freedom. The use of the fully-developed trefoil and lobe is sufficient to indicate a very considerable Early English influence (see Fig. 2).

(4) The use of the pointed arch. This, however, cannot be taken as wholly good evidence; but as there is no apparent reason for the use of the pointed arch, it is included as evidence of Early English work. It is interesting to note that a round-headed Early English arch occurs in the chancel of this church, showing how little the form of an arch is to be depended upon as evidence of style.

(5) The bases of the southern capitals. These are interesting, but somewhat decayed; they are of a form which, taken alone, would be pure Early English. As shown in Fig. 3, they consist of a round, a deep hollow, and a larger round, the last answering the "water-holding" test. Attached to the lower member is a tongue covering the space made by the projection of the plinth. The form is perhaps more Norman than Early English, resembling to a certain extent some Norman foot ornaments at Malpas Church, Monmouthshire.*

Some similar examples occur in the Transitional bases in the corona of Canterbury Cathedral. The Orpington specimens, therefore, seem to be the stage between the Norman and Early English foot ornaments; not exactly like either, but bearing a resemblance to both, occupying precisely that mid-way position one would expect in a work of Transitional date.

As an artistic effort, the work is undoubtedly a success; there is just that sufficiency of detail requisite to convey an impression of richness without vulgar display. If any criticism may be offered, it is on the rather disturbing way in which the bold chevron-moulding forces its point on the inner pear-shaped member, and presenting a number of spots of shade rather than one continuous line of shadow. The Transitional architect had evidently not learnt to handle his moulding with the consummate skill of his immediate successors.

Having now drawn attention to the chief decorative features of this interesting doorway, it remains to deal with certain other details which have a sort of melancholy interest, inasmuch as, instead of being of a constructional character, they seem to have had a destructive object. It should be remembered that in the sixteenth century and later times man's efforts to preserve ecclesiastical art seem to have been in inverse ratio to the beauty of the objects with which he came into contact. There are two reasons for this—either a hatred of anything having any connection with pre-Reformation times, or a hatred of art for its own sake. The results of both species of intelligence are fairly evident at Orpington.

The first structural alteration in the door was made during the fifteenth century, when the south pillar was mutilated to an alarming extent in order to insert a stoup. To do this it was seemingly considered necessary to entirely remove about 3ft. of the shaft, and also the faces of at least six jamb-stones. The alterations, too, may possibly have caused the mutilation of the capital, all detail of which has disappeared.

As the doorway now stands it is evident that it has received most unfair treatment. Not only are the capitals and bases much damaged, but the tooth ornaments have received odious attention. Out of about ninety individuals forty-three have been removed either by the slow process of time or, as one shrewdly suspects, by human agency in the sixteenth century. But these unfortunate fanatics must not bear all the blame; on the door-jambs and shafts are scribbled in decrepid writing the initials and

---

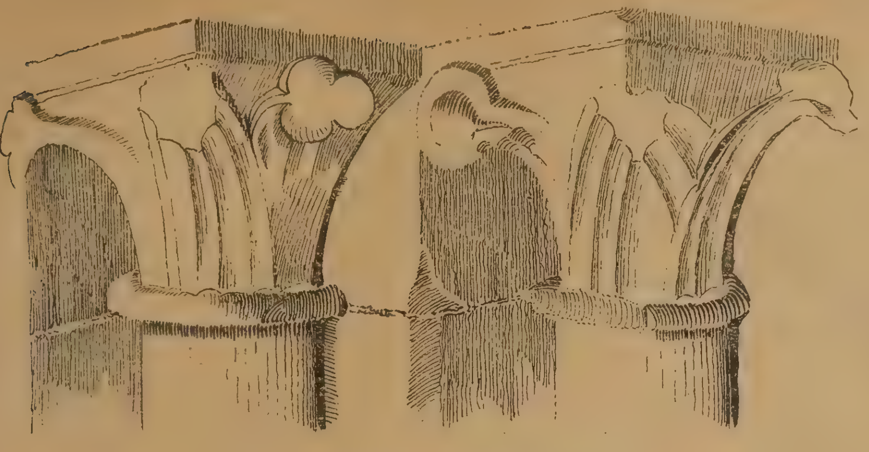

FIG. 2.—CAPITALS OF NORTH JAMB.

names of those poor people who may some day fall into the hands of the long-suffering antiquary. Another particularly annoying piece of modern foolishness is the scratching of crosses on doorways in mere imitation of the ancient consecration cross. On the south jamb of the Orpington door, and about 4ft. from the ground, is the genuine consecration cross accompanied by some modern imitations; a careful examination by the aid of a magnifying glass will generally reveal the difference between the genuine cross and the modern counterfeit.

The foregoing remarks touch all the important points of this interesting doorway, and perhaps show that the work of the years 1170–92, although not at all suitable for modern reproduction, is at least worthy of careful study and complete mastery; one may go further and say that without a good knowledge of Transitional features it is extremely difficult to properly grasp the beauty of the style to which it led. If it be possible in these times to produce work approaching the technical excellence of the Early English style, surely one way to make it a living and attainable idea is to give a discriminating study to the sources from which that period derived its first inspiration. The course of Transitional art is both interesting and valuable—interesting, as showing the gradual awakening of a great factor in architectural design; and valuable, as from its failings the modern worker may avoid the pitfalls of the ancient architect, who felt the power of the new style but fell short of the perfect in the expression of his ideas. It is to the application of the Transitional artists that we owe the successful issue of the "battle of the styles" in such buildings as Lincoln and Wells, and countless other churches enshrining some gem of Early English art which is too often but little appreciated by those to whom the stewardship is entrusted.

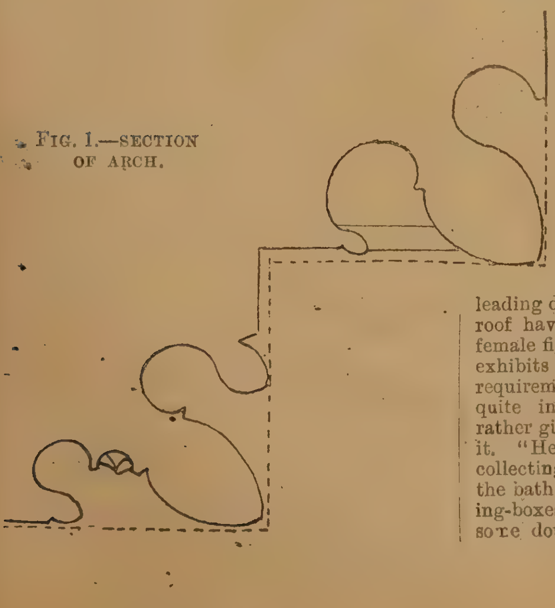

FIG. 1.—SECTION OF ARCH.

R.I.B.A. PRIZE DRAWINGS.

THE drawings submitted for the several studentship prizes of the Royal Institute of British Architects are on exhibition till January 25th at the Alpine Club (entrance in Mill Street, Conduit Street, W.). A very excellent subject was set for the Soane Medallion and £100—that of a swimming bath for men in a seaside town. It is most desirable in competitions of this nature that the students should be required to exercise their talents on something which is likely to come within their sphere as practising architects, and this year the subject chosen is eminently satisfactory in this particular. Sixteen sets of designs have been sent in, and they show a vast range of treatment, from the ordinary pitch-pine and iron tie-rod order to sculptured halls of Roman magnificence: which is the result of the cost of the structure being unstated in the conditions. There is not one design which fulfils all requirements, but several of them exhibit points of interest. "Roma," for example, has carefully considered details in regard to the bath being covered over in the winter and used as a place for concerts or other entertainments; and his provision of a covered shelter at one side of the building leading to the gallery stairs is most commendable, as the usual access to the gallery is very inconveniently arranged. This design is conceived in a sumptuous style, marble columns, mosaic and tiles being used generously, and on the whole the effect of the interior is good. "Iona" is another praiseworthy design, but the plan is much more elaborate, comprising, amongst other accommodation, the full equipment for Turkish baths and slipper baths, as well as a salt-water bath and a gymnasium at the back of the swimming bath proper. This design is even more elaborate than the last, the extensive carving and statuary in the interior recalling very strongly the old Italian masters: the drawing itself is excellent. "Zeno" shows a totally different treatment, being much less costly to execute. The building is of red brick and the girders are carried boldly across the inside, the gallery front being embellished with ceramic panels that remind one of Pompeii; the effect of the whole is, however, cold and uninteresting, though the plan has the excellent feature of a passage behind the dressing-boxes to prevent people walking in boots along the side of the bath. The design by "Phœnix" has an apsidal termination enclosing hot-water fountains (though for what purpose is not obvious); "Amphibious" is distinctly Venetian, four steps leading down to the bath edge all round and the roof having corbels or brackets in the form of female figures about to dive into the bath—which exhibits ingenuity, but does not satisfy æsthetic requirements, as the figures in that position are quite incapable of supporting the roof, and rather give the impression of being supported by it. "Hero" employs the inconvenient device of collecting all his dressing-boxes at one side of the bath; "Io" is very generous with his dressing-boxes, providing about eighty; "Nero" has some double columns which, though doubtless imposing, quite preclude the persons sitting in the gallery between them from seeing more than a quarter of the bath-space at one time; "Wyvenhoe" covers his bath with a great lattice-girdered roof, which is well devised, while at intervals along the bath sides are figures holding lights in their hands (it is desirable to call attention to this feature, as the artificial lighting of the bath is apparently forgotten by most competitors). Of the remaining designs none call for special mention. A feature which has proved a Gordian knot to all is the chimney stack. "Roma" has done as well as any in making a water-tower of it, with the stack at one side, but this tower looks very stunted. We think it would have been better if a limit to the cost had been stipulated, which would have prevented so large a difference in the accommodation provided by the various competitors; but, in any case, it is obvious that no seaside town would incur the expense of erecting several of the designs, and this fact should have been apparent to their authors.

The Tite Prize (certificate and £30 for travel in Italy) has attracted many students this year. The subject was, "A Royal Memorial Chapel in the Italian Style"; and twenty-four designs have been submitted. The plan consists of seven radiating chapels arranged around a central hexagonal space, and the similarity of the designs is remarkable. Each student—almost without exception—seems to have taken as his model—St. Paul's Cathedral. The result is that we have a generous duplication of Wren's dome and western front, but without its delicacies of proportion. One or two competitors are frankly Italian, and it is not difficult to name their models. This is much to be regretted, as the subject is one of wide scope. Even considering the object for which this prize was founded, it would have perhaps been better if the style had not been restricted to "Italian," and the student

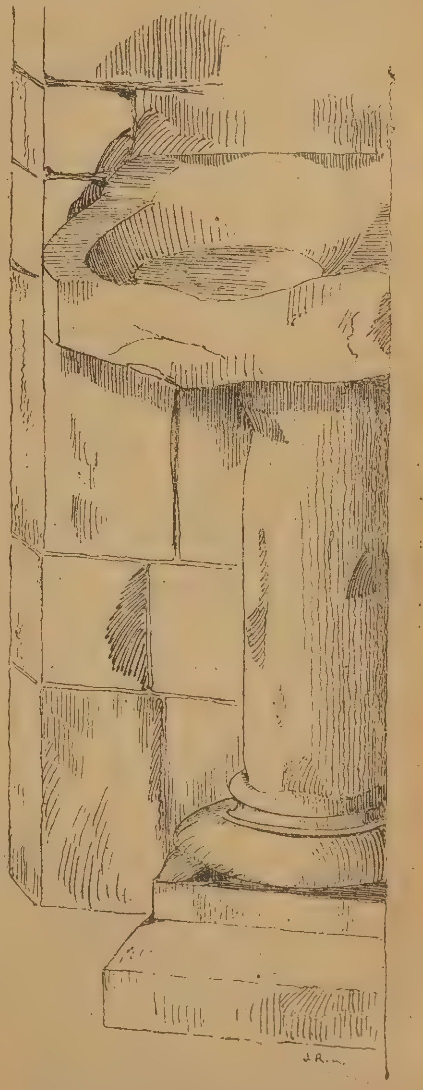

FIG. 3.—DETAIL OF SOUTH JAMB.

thus allowed to develop a creation of his own instead of merely producing copies in miniature of existing buildings.

Twelve sets of drawings for the Pugin Studentship (silver medal and £40 for travel in the United Kingdom) have been submitted, but on the whole they are not very good. Mr. C. Wontner Smith's drawings are, however, excellent, the colour-work being clean and sharp, and the rest exhibiting a painstaking and very firm hand.

The subject set for the Grissell Prize (gold medal and £10 10s.) was, "a roof, in iron, concrete and glass, of a picture gallery." The few designs submitted call for no special mention; nor do the two sets of drawings submitted for the Godwin Bursary (silver medal and £40 for travel outside the United Kingdom) or the twelve sets of measured drawings sent in for the Institute Silver Medal and £10 10s. Many careful drawings are sent in for the Owen Jones Studentship (certificate and £100 for travel and study of colour). Amongst the drawings exhibited are those by Mr. George A. Paterson (Owen Jones Student, 1900), Mr. Henry W. Cotman (Pugin Student, 1901), and Mr. Sidney K. Greenslade (Godwin Bursar, 1900).

Views & Reviews.

Water-Supply.

Dr. Thresh has produced a very valuable work on the important subject of water and water-supplies, and its usefulness can be gauged from the fact that the present is the third edition. To the medical officer of health it is invaluable, but to the water engineer and architect only so far as it deals with the composition, analysis, purification and selection of water, and the law relating thereto; but the information afforded upon the construction of wells, reservoirs, &c., planning of buildings and the laying-out of distribution schemes, pumps and pumping machinery, and such constructive parts of water-supply schemes, is of the most meagre sort. The illustrations are very few and useless. These defects should be remedied, as there is need for a good constructive work on the subject. Of course, water-works engineering is not in Dr. Thresh's line, but he should secure the co-operation of a qualified engineer; the want of this detracts from an otherwise excellent book.

"Water and Water Supplies," by John C. Thresh, D.Sc., M.D., D.P.H., F.I.C., &c. London: Rebman, Ltd., 129, Shaftesbury Avenue, W.C. Price 7s. 6d. nett.

The Chemistry of Painting Materials.

The third edition of Professor Church's book has been thoroughly revised and enlarged, and should be in the hands of every colourist. Of course the book is almost a necessity to any oil painter of pretensions, but it is also of great value to the architectural draughtsman and water-colourist. The book is divided into chapters on painting grounds, vehicles and varnishes, pigments and "methods and results." Mr. Church, as Professor of Chemistry in the Royal Academy, has had exceptional opportunities for studying his subject for many years. If there is one criticism to make on the book it is that a chapter dealing with the principles of colour-mixing and testing should be included. The analyses of drawing-papers on p. 9 are too old to be of value.

"The Chemistry of Paints and Painting," by A. H. Church, F.R.S., M.A., D.Sc., F.S.A. Third Edition, revised and enlarged. London: Seeley & Co., Ltd., 38, Great Russell Street.

Guy's Hospital is being renovated and added to. A new nurses' home is nearly finished. It will be the largest and most complete building of the kind in the country, and will contain 210 bedrooms, reading- and dining-rooms, and a swimming bath. A laundry is also being provided, though much of the cost has yet to be defrayed. The lighting and heating systems of the hospital are being reconstructed. The casualty department will be extended and renovated. The system of open-air balconies into which patients from the wards can be wheeled in fine weather, so that they may enjoy the fresh air and the sunshine, will be extended, and sanitary blocks for the surgical wards provided. The improvements will cost £180,000.

ARCHITECTURAL ASSOCIATION.

ARCHITECTURAL AND CONSTRUCTIONAL ENGINEERING.

BY T. C. CUNNINGTON.

A MEETING of the Architectural Association was held on Friday evening last at 9, Conduit Street, W., the chair being occupied by the president, Mr. Howard Seth-Smith. After the minutes of the last meeting had been read and confirmed, the following were elected members of the Association:—E. J. Harbottle, R. Herbert, J. R. Hobson, L. de B. Kilsey, E. P. Lee, A. G. MacNaughtan, H. A. Porter and W. S. Read. The president announced the following additional donations to the New Premises Fund:—

	£	s.	d.
Robert L. Curtis - - - - -	105	0	0
R. A. Briggs - - - - -	12	12	0
John Leaning - - - - -	10	10	0
H. J. Leaning - - - - -	5	5	0
H. Passmore - - - - -	5	5	0
E. Boehmer - - - - -	2	2	0
M. F. W. Bunney - - - -	2	2	0
Guy M. Nicholson - - - -	2	2	0
C. E. Simmons - - - - -	2	2	0
C. M. C. Armstrong - - - -	1	1	0
D. Stewart - - - - -	1	1	0
G. H Smith - - - - -	1	1	0
P. Rider Smith - - - - -	1	1	0
F. J. Potter - - - - -	1	1	0
W. B. Dukes - - - - -	1	1	0
	153	6	0
Donations previously announced	3,436	12	0
Total - - -	£3,589	18	0

It was announced that the First Spring Visit would take place on February 1st at 2.30 p.m. to Christ Church, Brixton Road (near Kennington Park), by kind permission of Prof. Beresford Pite. Mr. T. C. Cunnington then read a paper on "Architectural and Constructional Engineering." He said:—

In the first place I propose to deal with American tall structures, and then give some examples of roofs executed to fulfil specific requirements.

With all the ingenuity and the economy of time and money incident to its application, it must be admitted that the so-called Chicago raft foundation cannot be recommended for use upon compressible soil, by reason of its liability to serious disturbance by future underground works in adjacent or neighbouring streets; but that the footings should be carried through the compressible strata to the underlying rock, and for this purpose timber piling cannot be trusted as affording a guarantee of safety for many years, unless there is absolute certainty of maintenance of water-level in the underlying soil. This will, in many cases, make concrete piles, or caissons containing masonry or concrete piers, the only scheme of foundation construction which warrants the permanence of the supports of the structure.

The first building I propose to describe will be

The Park Row Building, New York,

Mr. R. H. Robertson being the architect and Mr. Nathaniel Roberts the engineer, the latter being responsible for the whole of the structural steelwork. The building is twenty-six storeys high in the middle part, while the two towers are each four storeys higher, making in all thirty storeys. The total height from the kerb to the top of the cupolas is 386ft. The structure is carried entirely on piles driven into a sand foundation to a depth of about 20ft. There are about 3,500 piles used in the construction. They are of *round American spruce* (free from knots, with the bark left on). They are from 10in. to 14in. in diameter at the head, and the load on each does not exceed 16 tons. They are driven at from 16in. to 18in. apart, centre to centre, commencing at the centre of each group and working outwards, while the rows are about 24in. apart, centre to centre. The heads are cut off below the level of ground-water, or at 34ft. 4in. below the level of the kerb in Park Row. From 12in. to 16in. is excavated out around the head of each pile, which space is filled in with concrete composed of 1 part Portland cement, 2 parts sand, and 5 parts broken stone of not more than 2½in. cube. The concrete is levelled up flush with the heads of the piles. Upon the top of the concrete are laid granite blocks to receive the brick piers which carry the grillage beams to be described later.

The column loads carried by the foundations of this building are very high, some of them exceptionally so. It was, therefore, necessary to distribute the pressure on the grillage beams as evenly as possible. The need for great care in this matter will be evident when I say that the weight of the steelwork alone is 9,000 tons, while Mr. Roberts estimates that the weight of the building is 56,200 tons, or a total of 65,200 tons.

Most of the columns rest on distributing girders, each girder carrying, as a rule, two

HENLEY TOWN HALL. HENRY T. HARE, F.R.I.B.A., ARCHITECT. W. LINDSAY AND CO., ENGINEERS. (*Photo: S. B. Bolas & Co.*)

columns, though in one case there are as many as four columns on one girder. The interior columns have no distributing girders, but rest directly on the grillage beams, and have each an independent foundation. Each foundation was separately designed for the load it had to carry, and the sizes of the girders and the grillage beams vary accordingly.

(A typical distributing girder was here described by the lecturer. This girder supports columns each of which carries about 1,100 tons, so that the girder itself sustains a load of about 2,200 tons. It is 26ft. long and 8ft. deep, and has four web plates, each ⅝in. thick. There are four angles, 6in. by 6in. by ⅞in., in each flange, together with three plates, each 2ft. 8in. wide by ¾in. thick. The girder is carried on thirty-five joist beams 12in. deep and 5ft. long, which are separated by distance-pieces. In the foundation in question there are four of these distance-pieces between every two beams, but in some of the foundations, where the length of the beam is 6ft., there are six distance-pieces between every two beams. The distance-pieces are box-shaped, and have milled surfaces which bear evenly on the top and bottom flange of the beams. The grillage beams rest on the top of the granite caps, and are bedded on cement. The largest distributing girder is that carrying the four columns facing Theatre Alley. It carries a load of about 2,930 tons, and weighs 47 tons. In the manufacture of all the distributing girders it was particularly specified that the vertical angle-iron stiffeners should have a good bearing against the top and bottom flanges.)

The floor beams are generally composed of the joist-beams bolted together with ¾-in. bolts, and have cast-iron distance-pieces between them. There are three or four distance-pieces to each span, and they are so made that the flanges of the joist beams will not be less than 1½in. apart. The beams which carry the fireproof flooring are all tied together with ¾in. bolts to take the thrust of the flat arches. The floor beams are framed so that the bottom presents two different levels, one 5in. above the other. In the area, where 15-in. beams are used, the beams and girders are framed flush, the 10in. and 12in. beams being framed flush at the bottom, which is 5in. above the bottom of the 15in. beams.

Box and lattice girders are used for connecting the columns at the walls, and they are attached to the columns in such a way as to make the connections as stiff as possible, in order that it may do service as vertical wind-bracing.

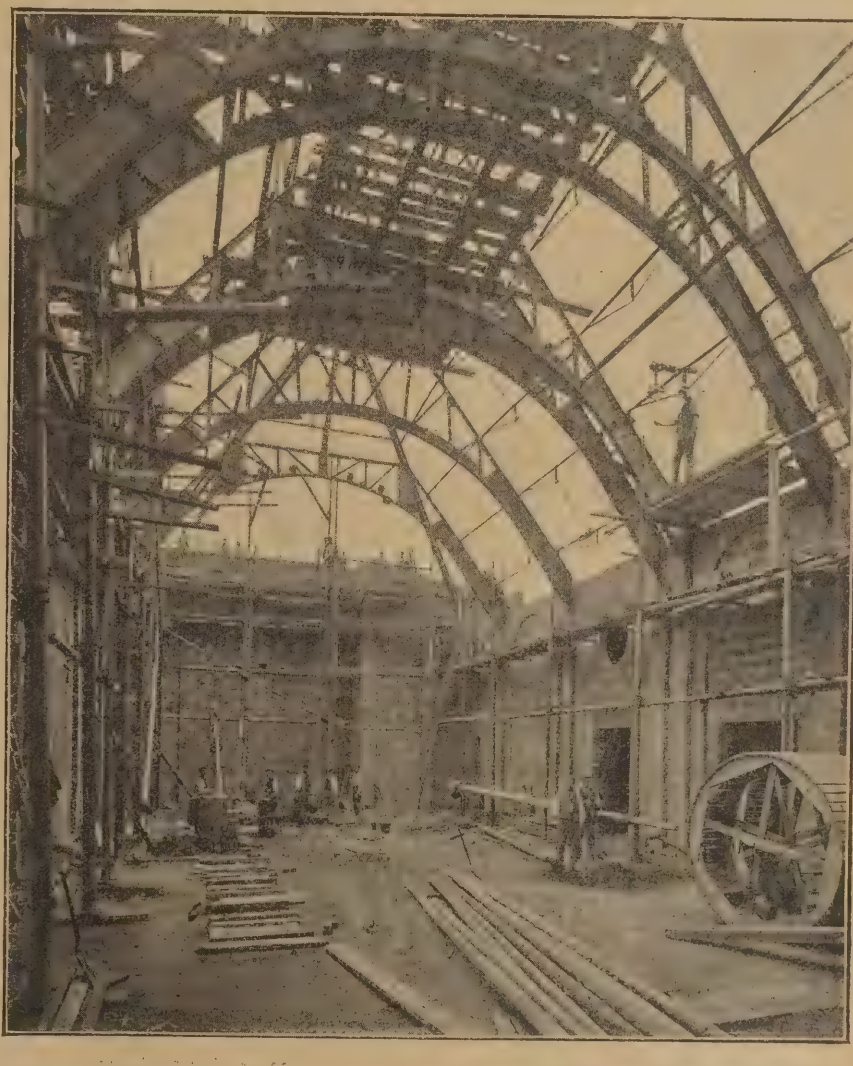
The bottom length of each of the main columns, where it rests on the distributing girder, has a flange plate at right angles to its axis, which plate is securely riveted to the body of the column with angles by means of a double line of rivets, while at its upper end, where the next column length rests, it has angles forming a flange, but no plate. The ends of the two lengths of columns are faced so as to bear very truly one on the other, and are riveted together through each angle. In addition to this there are two splice plates, one on each side of the column. These plates are firmly riveted to the lower length in the shops, but the part projecting above the top is riveted to the next length of column above when they are erected on the site of the building. These rivets pass through the splice plates and the sides of the column. This forms a very strong joint, and is preferable to the method of fixing by means of angles alone, as it makes the whole column much stiffer and better able to resist the side stresses due to wind.

All the columns in the walls are carried up 3ft. above the roof beam, and are there connected with a line of 8in. channel under the coping.

The Montgomery Ward & Co.'s Building

at Madison Street and Michigan Avenue, in the heart of the Chicago business district, was next described by the lecturer.

The concrete foundation piers are set on steel grillages on about 1,200 15in. piles. These are 52ft. long, driven to 68ft. below grade, and are calculated for maximum loads of 25 tons each. The steel columns are of closed rectangular cross-section, made up of pairs of channels and flange cover-plates, the largest having an area of about 180 sq. in. of steel. The tower is calculated for a wind-pressure of 30lbs. per sq. ft. on its vertical projections above the main roof, and the remainder of the building is calculated for the same wind-pressure on all exposed vertical surfaces of the two end bays of each elevation. The wind stresses parallel to Madison Street are assumed to be resisted by the rigidity of the walls, floors, and partitions, and by the strength of the beam and column connections. In the direction parallel to Mitchigan Avenue there is special wind-bracing, consisting of solid plate stiffened knee-braces at the top and bottom of each end of the wall girders, and of horizontal plate girders, 30in. deep, with 6in. by 4in. flange angles, at every storey between the corner column and the one adjacent to it. A similar construction on all sides of the tower is carried up to the twentieth storey, where the knee-brace brackets are replaced by longer and heavier knee-brace struts connecting the tops of the corner columns to the system of plate girders which forms a rigid horizontal framework supporting the overhanging twentieth floor.



COLCHESTER TOWN HALL. JOHN BELCHER, A.R.A., ARCHITECT. W. LINDSAY AND CO., ENGINEERS. (*Photo : S. B. Bolas & Co.*)

There are twelve outside columns and no interior ones in the tower.

Up to the eighteenth storey its floor framing consists of two 24in. transverse joist-beams supported on the two pairs of intermediate columns, and of seven longitudinal lines of 8in. joist-beams, which are supported by these girders, and by the pairs of 15in. wall-girder channels which connect the columns in four places by direct connection to the intermediate columns. A 9ft. by 10ft. panel in the middle of the floor has additional framing for the circular elevator shaft. At the eighteenth storey light channels, beams, and angles are bracketed out a short distance from the columns just above the floor line to carry a projecting terra-cotta belt-course.

After describing the electric tower of the Pan-American Exposition, the lecturer dealt with

Wind-bracing.

In arranging a building for wind-brace sections, sometimes the floor plans will permit a symmetrical arrangement of the cross-section in which the wind-bracing is to be put. Frequently, however, no such desirable arrangement is possible, and only certain sections can be utilised. This complicates matters somewhat, but careful study will usually permit a satisfactory solution of the problem.

Wind-bracing in a high building performs, during and after erection, the very practical office of facilitating erection by enabling the columns to be maintained in their correct vertical position. Wind-bracing can be made of certain lengths to fit between the columns, and requires that each column shall be in its proper place before the bracing will fit, so that no great error can accumulate.

A careful comparison of the treatment of wind forces as applied to tall buildings of to-day leads one to the conclusion that the designers differ very materially in regard to the forces to be resisted, the strength of material employed, and the most efficient details of construction.

A building constructed with a well-proportioned iron frame should be safe if provided with brick partitions, or if the base is a large proportion of or equal to the height, or if the exterior of the iron framework is covered with well-built masonry walls of sufficient thickness, for the rigidity of the solid walls would exceed that of a solid frame to such an extent that, were the building to sway sufficiently to bring the bracing into play, the walls would be damaged before the rods could be brought into action. Hence the stability must depend entirely either upon the masonry or on the iron framing, and in veneer buildings, which are being particularly considered, the latter system of bracing the metal work must be used, with the walls as light as possible, simply enclosing the building against climatic and injurious forces.

Wind-bracing must reach some solid connection at the ground. It should also be arranged in some symmetrical relation to the building outlines.

The shears are undoubtedly reduced to some considerable extent through many practical considerations, having regard to the dead weight of the structure itself; the resistance to lateral strains offered in the stiff lateral riveted connections between the floor system and the columns, the stiffening effects of partitions (if continuously and strongly built) and linings, coverings, &c., all tend to decrease the distorting effects of the wind-pressure.

Take a typical skeleton building fourteen storeys high, 12ft. each, 24ft. front, and columns spaced 12ft. apart in the depth of the building.

Assuming that stiffness against side yielding alone is necessary, and utilising floor girders as struts with the columns as chords, at 30lbs. per sq. ft. wind-pressure the panel load equals 4,300lbs.; considering the protection afforded by neighbouring buildings, the point of application of the resultant wind-pressure will be taken at say two-thirds of the height of the structure above ground. The total shear will then equal about 60,000 lbs. or 30 tons.

The dead weight, including iron walls, floors, filling, &c., will equal about 250 tons for one foundation, while even for a building with no filling or partitions completed, the dead weight is still some 200 tons, thus rendering anchorage unnecessary.

Exterior Walls—Piers.

The weight of the walls is capable of at least three separate treatments, each suited to its own peculiar circumstances:

1. Where the outside piers are constructed entirely of masonry carrying all of the wall, floor and roof loads which come upon them, by means of masonry alone. Such construction is used in buildings of moderate heights, and constitutes the ordinary type of building.

The objections to such piers of solid masonry are threefold, where structures are higher than, say, sixteen storeys, viz.:—

(*a*) The modern requirements of plenty of light and air in all offices demand that the windows be broad and numerous and the piers narrow.

In the highest buildings of the present day hardly any masonry construction is strong enough to carry the necessary roof and floor loads besides its own weight for so great a height and with so small a cross-section as is desired.

(*b*) The second objection to such large masonry piers is that they take up too much valuable renting space, and where the rent of offices is proportioned at per sq. ft. this becomes a matter of no inconsiderable importance to the owner. Also, the weight of these solid masonry piers would so add to the load per sq. ft. that many of the most remarkable examples of architectural engineering would be well nigh impossible.

2. The second treatment is that in which metal columns carrying the tributory floor and roof loads are placed inside the masonry piers, while the latter support themselves and the "spandrels" only. The spandrels constitute those portions of the exterior walls lying between the piers and over and under the window spaces.

3. The third method of constructing the exterior piers is the one more approved at the present stage of architectural engineering, the one which has undoubtedly opened up the means for building the highest structures. In this all the weights are thrown on the metal columns, which, in place of solid piers, are surrounded with a protective shell or covering only, made of ornamental terra-cotta or brickwork securely anchored to and supported by the columns at the various floor levels.

Roofs.

The Buffalo Savings Bank occupies a rectangle of about 75ft. by 69ft., with a triangular extension 56ft. long on one side. The building consists of a two-storey main rectangular part, about 130ft. high, and a three-storey wing, about 50ft. high, on the triangular extension of the plot. The banking-room, 65ft. high, is surmounted by a domed ceiling supported on an octagonal steel framework. Above the dome there is a steel platform supporting an octagonal office storey, 11ft. high and 70ft. wide, which is surmounted by a domed roof 53ft. 6in. in diameter, and 33ft. high above the horizontal ceiling.

In the New York Clearing House the dome has a nearly hemispherical exterior surface, and is supported by an octagonal arrangement of web-connected plate girders. It rests on each of these girders, and intermediately on 20in. rolled beams across their angles, which form with them a sixteen-sided polygon. The girders are supported on the tops of the columns at the angles of the octagon except on one side. Here the 16ft. side of the octagon is the middle part of a 47ft. riveted truss, which carries the ends of the adjacent girders, and is supported on special columns. This truss has a double-triangular web system, with all connections riveted. The tension diagonals are flat plates; the bottom-chord web-plates are 18in. deep, and the fourth-storey floor-beams are connected to the webs.

The vertical end members of the truss are practically continuations of the columns that support it. These columns are spliced at every storey with four web-plates. The bottom of the lower section has eight vertical connecting angles riveted to the vertical web stiffener-plates of the extended base, the base being 5½ft. square, with eight vertical web stiffener-plates and four knee-brace angles on the main diagonals to stiffen the corners. Other columns have bases 3½ft. square, which are similar to these, except that the knee-brace angles are omitted. There are sixteen radial dome trusses.

Colchester Town Hall Roof.

The roof over the Moot Hall, about 100ft. by 40ft., is constructed with seven principals, the ends of the roof being hipped. The high pitch and the conditions to be complied with necessitated nominally two different systems of trussing. There are two pairs of principals placed 3ft. 1½in. centres. This method was adopted to carry the fire and ventilating flues from the lower storeys to the chimney-stacks that are placed on the front slope and near the ridge line, the flue pipes in same being embedded and surrounded in concrete. Seating angles and connecting plates are riveted on the intrados of the principals to receive the wood purlins or framework for the barrel-vaulted ceiling. The principals are made of double angles 4in. by 3in. by ⅜in., and ⅜in. web plates in the lower part or legs, well stiffened and riveted together. The hip rafters are also made of plates and double angles, so as to receive the purlins and other framing. These principals bear upon the front wall masonry and in the opposite wall upon specially-built steel stanchions, to which they are riveted. These stanchions stand upon steel plate girders at the floor level of the Hall, the girders being supported by compound stanchions made up of joist and plates, and extend to below the lower basement floor level. The purlins are 3½in. by 3½in. by ⅜in. angles, and trussed, to which are bolted the wood purlins that receive the roof boarding.

Henley Town Hall Roof.

Henley Town Hall roof is constructed with six steel principals, Mansard-shaped outside or extrados, and semi-circular on intrados. Each principal was made in three sections for convenience of transit (the span being 40ft.). They are bolted on the radial line at the junction where the sloping roof meets the horizontal. They are made of tees, angles, bars, and plates riveted together. Angle seatings and cleats are provided on the intrados to receive the purlins or the principals of the framing.

The Discussion.

The president read letters from Mr. A. T. Walmisley, Mr. Macvicar Anderson and Mr. Riley regretting their inability to attend the meeting. Mr. Walmisley remarked that he thought there were many structures where the engineer might profitably engage the services of an architect for the artistic portions and general arrangements of interiors as well as elevations, but that the structural parts to be designed by the engineer should in every case claim the precedence and dictate the outline of design. He cited the arch of Westminster Bridge. An engineer knew that no diagram of stresses in ironwork gave the curve here adopted. He also cited the iron parapet of the Victoria Railway Bridge across the Thames at Battersea, which was admired by engineers because it was a design that could not be made in masonry.

A letter was read from Mr. Lewis Solomon, F.R.I.B.A., in the course of which he referred to iron domes. These the paper led him to believe were almost a new feature, but that was not so, as he remembered that more than thirty years ago, when he was connected with the construction of the Ottoman Bank in Throgmorton Street, that there was an iron dome to the Board room, the ironwork of which was, he believed, made by Mr. Homan (now of the firm of Homan & Rodgers), but the architectural work was in no way done by the engineer.

The following notes by Mr. W. E. Riley, superintending architect to the London County Council, were read to the meeting:—

Looking recently at some views of Lower New York they seemed quite unfamiliar to me although I was there frequently up to thirteen years ago. The erection of numerous high buildings has brought about this great change. In these buildings the steel columns are the only portions of the structure which are carried to the foundations, and they provide the reactionary forces of the weight of the building; each storey being carried independently of the one above or below it. The cubical contents of some of the high buildings in New York must necessarily be very considerable, especially in comparison with London buildings, where, as is well known, special permission is necessary to allow buildings of the warehouse class of a greater cubical extent than 250,000 cub. ft., in which cases the buildings must not exceed 60ft. in height, nor be of a maximum capacity of more than 450,000 cub. ft. But it must be borne in mind that American cities have been laid out on modern lines with the special advantage of enjoying a maximum of sunshine, whereas in London the limited amount of sunshine must be regarded as a factor in considering the height of buildings in relation to its open spaces. The newest building code of New York City, which came into operation in October, 1900, provides that any hotel, lodging-house, school, theatre, gaol, hospital, &c. which exceeds 35ft. in height shall be built fireproof, and every other building which exceeds 37ft. in height shall be similarly constructed. Mr. Riley referred to the fires at the Home Life Building and the Windsor Hotel, and said in conclusion that if the tall building was not all that could be desired, it was another effort to solve a difficulty, and as experience was gained it might ultimately lead to some satisfactory result in America; but it did not seem a suitable form of structure for this part of the world.

Mr. Thomas Blashill said he did not think it at all likely that tall buildings like those in America would be erected in this country, but there was much to be learnt from them, especially from the methods adopted for joining the details. Students should study ironwork construction more. The separate action of engineer and architect, neither of whom had much sympathy with the other, was not what should be desired. In concluding he referred to the action now being taken by the various engineering bodies for the standardizing of steel sections, which would prove of great value both to engineers and architects.

Mr. Max Clarke put several constructural questions to the lecturer with regard to the foundations. Mr. Richard Moreland, junr., A.M.I.C.E., then observed that he thought it would have been better to have used steel instead of granite blocks in the foundations. In London there were several large buildings which were floated on bad foundations in this way—the Harmsworth building, for example, where the load was calculated at 2 tons per sq. ft.; and also the Carlton Hotel block. At the former building, where all the basement space was required for the printing machines, solid steel columns had been used in place of hollow steel columns or riveted stanchions, both of which would have needed to be much larger in section He thought that the nearest approach to an American building in London was that of Messrs. Nicholsons, at the corner of St. Paul's Churchyard. Nobody would call it a beautiful building, but it was interesting as having no brickwork up to the second-floor level, all being carried on steel columns and the wall above cantilevered over. Architects were constantly wanting shallow girders. One-twentieth or one-twenty-fourth of the span was the usual practice, but if this limit was exceeded the greater stress should be allowed for.

Mr. H. H. Statham said he should respect the American architects more if they built more truthfully, leaving their steel structures uncovered by false veneers. The president remarked that when one considered the enormous rise in ground values, the increasing spans in domes, arches, &c., the precautions against the spread of fire, and other matters—these seemed to dictate some kind of development on the lines adopted in America; and he suggested that a compromise might perhaps be arrived at to suit the needs for large buildings on small areas. Mr. Cunnington replied, and the meeting then terminated.

Law Cases.

Electric Street Inspection-Boxes.—At the Guildhall Police Court last week the Charing Cross and Strand Electricity Supply Corporation, Ltd., was summoned by Mr. Edmund Woodthorpe, district surveyor for the northern division of the City of London, for beginning certain works without having served a notice upon him. Alderman Crosby, in giving his decision, said the work was an electric street inspection-box, and he found that the Company had not given notice in accordance with section 145 of the Building Act. He held that this was a building, structure or work within the meaning of that Act, and fined the company £2 and £2 2s. costs. Defendant's counsel asked the Court to state a special case, but the Alderman refused to do so.

Recovering Cost of Repairing Highway.—On January 12th, in the King's Bench Division of the High Court of Justice, judgment was given in the case of the *Urban District Council of Esher and the Dittons* v *Marks.* The action was brought to recover £137 10s. 5d., being the necessary expenses incurred by the plaintiffs in the repair of a certain highway known as Ember Lane, leading from Bridge Road, Thames Ditton, westward to the bank of the River Ember, which highway the plaintiffs alleged that the defendant was liable to repair *ratione tenuræ* and had failed to repair after due request, pursuant to the provisions of the Local Government Act, 1894, section 25, sub-section 2. It was contended on behalf of the defendant that a liability to repair a highway *ratione tenuræ* can exist by prescription only, and therefore that where the road in question can be shown to have been first made within the period of legal memory there can be no such liability; and that as Ember Lane did not exist as a road before the year 1773 the defendant could not be liable to repair it *ratione tenuræ.* Judgment was, however, given for the plaintiffs.

Damage by Lightning: An Arbitration Case.—An enquiry was held at Chatham on January 10th by Mr. Alfred Hands, F.R.Met.Soc., in reference to a claim by the Churchwardens of Holy Trinity Church, New Brompton, against the insurance company for damage alleged to have been caused to the spire of that church by lightning on some date unknown. Some stones having fallen in July last, an examination was made, and cracks being found of such a nature as to render immediate repairs necessary, the work was carried out and compensation was claimed under the fire policy, which, as usual, contained a clause including lightning risks. The company having disputed the claim, Mr. Hands was appointed arbitrator, and after hearing expert evidence on both sides and examining the broken stones which had been preserved for the purpose of the enquiry, decided that the damage was not caused by lightning, but was due entirely to the rusting of the vane rod which passed through the stones, and, therefore, that the insurance company was not liable.

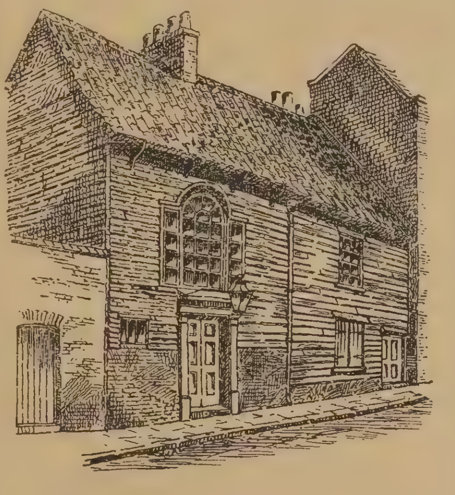
Bricks and Mortar.

APHORISM FOR THE WEEK.

Art excites enthusiasm and the critical faculty, the senses and the reason.—GUIZOT.

Our Plates. THE design for a town hall for a London borough by Mr. F. Winton Newman was the most monumental one sent in for the Royal Academy Gold Medal and Travelling Studentship in Architecture. The author decided that the town hall should to some extent dominate the whole design. The site he imagined to be on the borders of one of the London parks, and in working out the design he kept these points in view. The hall—with entrances, cloak-rooms, &c., is arranged on the ground floor, separate from the municipal portion of the building, so that it could be used without disturbing the working of the council-chamber or municipal offices. The latter are arranged on the ground- and second-floors, with additional rooms in the basement, the whole of the first floor being used solely for council-chamber, committee-rooms, mayor's room, &c. Access to the public gallery of council-chamber is by means of the staircase next to the rates office.—The house by Mr. Elmer Grey is a most admirable piece of simple design by this well-known American architect, and we publish it in pursuance of our policy of illustrating the best modern work on the other side of the Atlantic.

"Bunyan's Chapel." HALF-WAY down Great Suffolk Street, which is in the Borough, are two little courts of very little houses which are called King's Court and Queen's Court.



"BUNYAN'S CHAPEL," BOROUGH, S.E.

King's Court, like the Marshalsea, is to make way for modern improvements; and the most interesting monument in its narrow boundaries will shortly be pulled down. The monument is an odd little building, half wood and half red tiles, and both tumbling down, which is known as Bunyan's Chapel. Within, Bunyan's Chapel shows fewer symptoms of decay. The wooden galleries are there, as they have been for more than two hundred years, and the beams and rafters are sturdy. In its pulpit tradition alleges that Bunyan preached during the twelve years of his imprisonment at Bedford; and in a curious secret chamber between the garrets of the adjoining house he is said to have concealed himself from his pursuers. On the other hand, the Baptists state that early in the eighteenth century the Baptist congregation of Southwark were accustomed to assemble in an old meeting-house in what was then Duke Street, and now forms the western half of Union Street. About 1773 this congregation was divided in itself on the question of Calvinism. One-half migrated to Zoar Street, and the rest established themselves in what is now known as "Bunyan's Chapel," in King's Court, opposite Bridewell, then "a kind of assembly, or club-room, originally belonging to a public-house." It was "fitted up as a place of worship" and opened in 1800 by the "General Baptist Society." It held about 150 persons, and was latterly used as a mission hall. The accompanying drawing is by Mr. H. J. Palmer.

The R. L. S. Memorial. THE committee of the Robert Louis Stevenson Memorial has issued a statement explanatory of the delay which has occurred in bringing matters to completion. The sum likely to be available for the purposes of the memorial was not of a sufficient amount to warrant any attempt to erect an open-air memorial, so permission was sought from the Board of St. Giles High Kirk, Edinburgh — the Scottish national Valhalla—for the erection of a mural monument within its walls. The work was entrusted to Mr. Augustus Saint Gaudens, "the only sculptor of note who had studied Mr. Stevenson from the life," who visited Edinburgh in January, 1899, for the purpose of studying the proposed site for the memorial. In May, 1899, his design was submitted to the executive and to the St. Giles Board, and was approved. In December, 1899, Mr. Saint Gaudens submitted a revised design, which was approved. He then decided to revert to his original design. His model was just about to be cast in bronze when, in July, 1900, Mr. Saint Gaudens became dangerously ill, and had to leave Paris for the United States, where he has since undergone several serious surgical operations. The marble framework was received in Edinburgh last May. But in June Mr. Saint Gaudens wrote to say that he was so anxious that the patine (a surface colouring obtained by chemical treatment and firing) should be to his satisfaction that he had ordered the bronze cast to be forwarded to him in America for inspection, as he had found it impossible to come to Europe that year. At the end of November he had just ascertained that the patine did not satisfy him, and the completed bas-relief suggested to him the desirability of modifications which would improve its appearance. For these reasons he is remodelling the design, and intends to have a fresh cast made. This alteration will postpone the completion of the memorial until the spring.

Art Industries of Florence. MR. PERCY CHAPMAN, British Consul-General in Florence, has lately prepared a report on the industries of the province of Florence. The art industries are of great variety. Thus, amongst the quarries are those of the *Verde di Prato*, or serpentine, which stone is used for ornamental purposes, for the repairs to the cathedral and city churches, and to some extent for vases, statuettes and similar ornaments. The working of the precious metals is of considerable importance, especially in the city of Florence. The Florentine goldbeaters enjoy a high reputation in the world because of the purity of their gold and the regularity and thinness of the leaf. In porcelain the Ginori factory, not far from Florence, is the chief. It was established in 1735 by the Marchese Carlo Ginori—that is, about the same time as the Sèvres works, and about twenty-five years after the Dresden works at Meissen. The Ginori factory limits itself to the production of objects of real artistic value, disdaining bad imitations and the article known in the trade as *camelote.* The Cantagalli factory is renowned for artistic majolica, especially for imitations from the antique, plaques for inscriptions, Della Robbia work, and the like; and there are two other factories engaged in the production of similar art work. Artistic furniture was a decaying art in Florence ever since the thirteenth century, but in 1845 it was revived by several excellent artists. The Florentine mosaic industry, which was once a speciality of the city that enjoyed a world-wide renown, is now greatly affected by the competition of inferior mosaics in softer stones, as well as by fashion. The working of ornamental stones, especially marble and alabaster, holds a considerable place amongst the industries of the province. This industry, like that in mosaics, is almost exclusively supported by the British and American demand.

Brechin Cathedral Restoration. THE restoration of Brechin Cathedral may now be regarded as an accomplished fact. It has several times suffered restoration, and the vandals do not belong to past centuries, for even as recently as 1805-1807 ideas of restoration and improvement appear to have been crude as to suggest the destructive tendencies of the art-despising irreverency of the Reformation. Arches were dislodged, capitals and pillars and corbels put out of shape. The outer walls were carried up as if for the utilitarian needs of a factory! A flat plaster ceiling shut out the glory of arched outline above; and as for a chancel, it was built almost out of existence. The object of the recent scheme was, "while conserving what still exists of the ancient fabric, to bring back by a judicious restoration as much as possible of its pristine beauty," and Messrs. John Honeyman, R.S.A., & Keppie are the architects for the restoration. As soon as the architects had started on their work they received various surprises. When the plaster ceiling was taken away it was found that the clearstory remained uninjured. Stone coffins were disclosed, and, greatest of all, there were found the foundations of what had evidently formed a Norman building on the site of the present cathedral. The variety of style has long been a puzzle to the archæologists. The chancel, however, had suffered least from the ruthless destruction of Time and vandal. It was a very beautiful and delicate piece of work of Early English work, and the fragment that remained has enabled the architect to continue the design through the restored part. The chancel is a thirteenth-century one, coeval, of course, with the building of the cathedral. The composition of the windows is repeated; the roof is of oak, embellished with carving, and the stone used is the very same as that of the original construction. A new porch has been placed at the principal entrance on the north side. Doors for egress are provided, one from the new north aisle and one from the south transept, in addition to the great western door, which has been left intact. As there was little left to guide the architect in the restoration of the aisles, this involved a fresh design. The outside walls have been brought down to their proper height and roofed over, and the result brings into relief the famous round tower. An organ case of ornate design, made of Karri pine, has been restored at a cost of £135. In the chancel there are no less than fourteen memorial windows. The communion table, made of fine oak, and the pulpit, were the gift of the Women's Guild of the congregation. The cost has been about £12,500.

Mr. Delissa Joseph is the architect of the blocks of flats to be erected on the site of Stratheden House, Knightsbridge.

Enquiries Answered.

The services of a large staff of experts are at the disposal of readers who require information on architectural, constructional or legal matters. Questions should in all cases be addressed to the Editor. The querist's name and address must always be given, not necessarily for publication.

Ordnance Survey.

CARLISLE.—W. E. C. writes: "Can you furnish me with any particulars of the survey just completed in the north of England? Does it confirm previous measurements in the last survey; are there any differences in the measurement of any of the base lines, and, if so, what are the differences?"

We forwarded our correspondent's letter to the Ordnance Survey Office, Southampton, and in reply the Director-General says that the questions are so vague that it is difficult to gather what our correspondent requires. "Beyond the revision lately of the southern portion of the West Riding of Yorkshire, no general survey has been in progress in the north of England during the last twelve months, and no base lines have been remeasured. If 'W. E. C.' desires information on any point, he should communicate with this office and specify clearly what he requires, when the matter shall receive attention."

Requirements in S.K. Building Construction Examination.

CAMBERLEY.—F. C. W. writes: "When sitting at the South Kensington examination in building construction, is it necessary to designate each particular part of a sketch or drawing by its correct technical term? For example, if required to give a section of a stone window-sill (elementary) there would be throating, weathering, groove for water-bar, &c.; should these terms be written against them in the sketch, whether asked for or not? Also, is a scale required to be given under each sketch?"

I do not think it is necessary to give technical terms unless the question distinctly asks for them. Suppose the examiner requires a sketch of a stone sill, as suggested. If the sketch or drawing is clear enough without written explanation, it should be sufficient. It is the business of the examiner to discover the amount of knowledge possessed by the examinee on the subject of the question. The examiner is not in the position of a person who needs to have the subject explained to him for his own sake, and elaborateness of answer should be studiously avoided. There is distinct danger to the candidate if he goes beyond the definite limits of the question, as in the case of the Scripture examinee who had successfully answered "Who was Saul, King of Israel?" but who added that he was "Saul (who also is called Paul)." If this redundant information had been correct, it could not have added to full marks; and, being incorrect, it merely damaged the candidate's reputation as a scholar of Scripture in the mind of the examiner. If scales are not asked for, they need not be given. Candidates should remember that the marking of questions is not the most exhilarating kind of work. In society one should avoid deserving the reputation of a bore—don't bore the examiner. You may be anxious to pass the examination. Within proper limits this will sharpen your wits, but the consequences of your answer should not be mixed up in your mind with the question. The particular question should wholly occupy your mind at the time. The manly straightforward attitude of mind which makes a good witness in a court of justice should also be that of an examinee at a written examination. J. P.

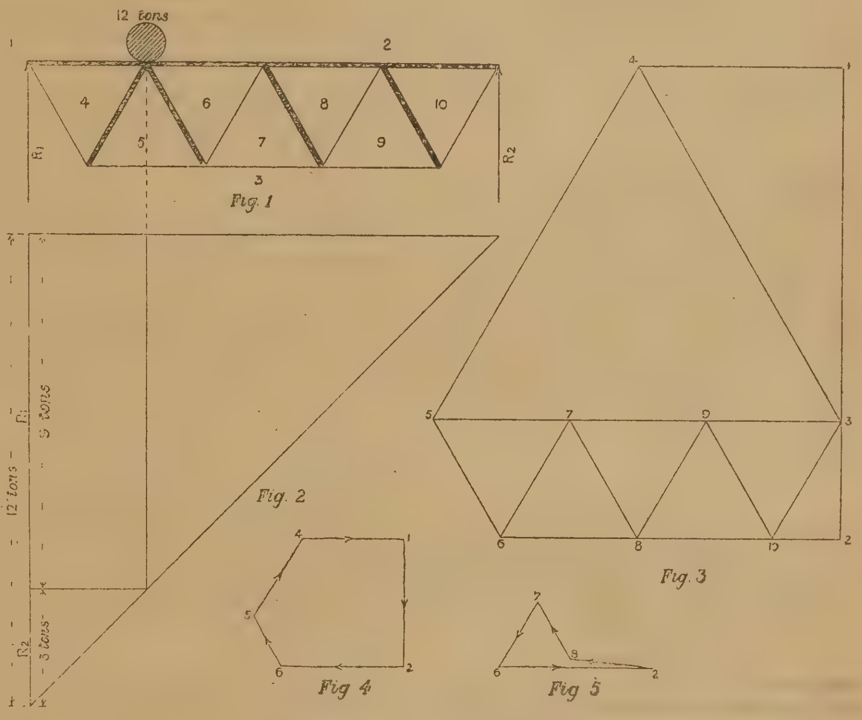
Ventilating Shafts.

EASTON.—VENTILATOR writes: "Having had a large experience in testing drains at large country mansions and other residences, I find that, when the atmosphere is heavy, with a very large number of ventilating shafts, although carried up to the ridge, the stench beats down and enters the house by the nearest open window. Can you suggest a remedy?"

There is nothing to prevent smoke or gases beating down under certain atmospheric conditions, but any nuisance arising from this cause is generally due to the fact that the chimney or ventilating pipe is too close to the window. The cheapest and best remedy is to add 5ft. or 6ft. to the height of the chimney or ventilating pipe. To avoid the risk of danger or nuisance from any issuing vitiated air, the top of a ventilating pipe should be arranged so as to be about 10ft. above any window, and in the case of dormer windows the ventilating pipe should also be carried up the roof until it has attained a horizontal distance of 5ft. or 6ft. to the rear of the window. T. E. C.

Stresses in Warren Girder.

LONDON, W.—J. P. writes: "There is a question in the Science and Art examinations which requires the candidate to determine graphically the nature and amount of stress set up in each member of a truss by the given load: scale 2 tons to an inch. This question would be very easy if there were a load at every point, but when there is only one load given at a certain point (as in the question) I can only work in the members which join that load at that particular point, which leaves more than half the truss with no stress whatever, and this seems impossible."



STRESSES IN WARREN GIRDER.

Let Fig. 1 be the skeleton elevation or frame diagram of girder. Below it draw Fig. 2, setting off the full load 12 tons and joining up the triangle. Then drop a line from the load in Fig. 1 to cut raking line of triangle and project horizontally to cut load line in the proportion of the two reactions R_1 and P_2. Now draw reciprocal diagram (Fig. 3) in the order of the numbering, the scaled lengths of the lines being the amount of the required stresses. To find the nature of the stresses, temporary arrowheads may be placed on Fig. 3, but it will be clearer to make separate sketches of the parts required, *e.g.*, for the stresses in the bars meeting under the load, take the required lines from Fig. 3 as shown in Fig. 4, and add arrowheads to show the direction of the consecutive lines from 1–2, which is known to be acting downwards. Then 2-6 is towards the joint in Fig. 1—therefore compression; 6–5 is towards the joint and therefore compression; and so on with 5–4 and 4-1, always going round with the clock. Now take the next joint, sketch the lines from Fig. 3 as in Fig. 5. Begin with 6–2, because the stress in this is known, and follow round with 2–8, 8–7 and 7–6. The advantage of the rough sketch for this purpose is shown by the separation of 2–8 from 6–2; they being really coincident. It will be observed that 7–6 is tension because it is acting away from the joint in Fig. 1.

HENRY ADAMS.

Architectural Appointments under Board of Works.

LONDON.—QUERIST writes: "To whom should I apply for information regarding examinations for appointments in the architectural departments of the Irish Board of Works and the English Board of Works?"

Consult the published questions of former examinations, issued by the Civil Service Commissioners, which you should be able to do at any good public library. These will give you a good idea of what is expected. You can form a fairly good notion of the probable yearly vacancies from the total number of men in the department you seek to join (say in a staff of thirty, one vacancy in the year). You will get an official, and more or less informing, reply to a letter addressed—in the case of the Irish Board of Works, to the Secretary, Board of Public Works, Ireland, the Custom House, Dublin; and in the case of the English Board of Works, to the Secretary, Works and Public Buildings, 12, Whitehall Place, London, S.W. When vacancies occur the examinations are advertised, but any candidate who seriously intends to compete, should specially prepare for the examination in anticipation of vacancies.

J. P.

Agreement not to Practise.

ALDA writes: "I was employed by a firm in Wolverhampton, and after being a year in their service I was asked to sign, and did sign, the following agreement: 'On consideration of your raising my salary from *x* to *x* per week I agree not to accept a situation with any firm in the same trade as yourselves within fifty miles of Wolverhampton.' I remained in their employment for two years after this event, and then, on account of private family business, was compelled to resign and go to Scotland. About five months later I was in a position to return, and offered my services again to this firm, but they were declined, my position having been filled in the meantime. Taking this action as breaking the agreement, I accepted a position in Birmingham; but on account of the Wolverhampton firm threatening proceedings I resigned and came to London, a Birmingham solicitor whom I consulted advising me that I had no case and that my only course was to leave the district. Does the agreement I signed now hold good, and is the firm entitled to keep me outside the fifty-miles radius?"

If the wording of the agreement was exactly as you state, it could not be enforced, for it would only hold good while you were in the firm's employ. The very comprehensiveness of the wording is, we think, destructive of their case. If, however, it was stated that in consideration of a sum of so many pounds being paid you in weekly instalments extending over a certain number of years or months you agreed to accept a situation as stated, and if this part of the contract was fulfilled, the agreement, we think, would hold good; but we do not consider, assuming your statement to be exact, that the firm could keep you out of any employment in the district.

Whitening Rough-Cast.

INGATESTONE.—R. H. B. writes: "In your last issue lime-white mixed with alum is advocated as the best material to use for whitening rough-cast. What should be the proportion of alum to lime-white?"

Make a thin solution of well-slaked lime with water; dissolve 1½lbs. of rock alum in boiling water; and add cold to each pail of lime-white.

Drainage Rights.

STUDENT writes: "Two semi-detached houses were the property of one owner for sixteen years, and then passed by will to different owners. After three years it has now been discovered that there is but one drain (or sewer) to the main sewer. Has the owner without drains acquired a right of drainage by means of the drains of adjoining house?"

Yes, the owner has apparently acquired a right to discharge his drainage into the drains of the adjoining house. T. E. C.

Cesspit for Cottages.

RADSTOCK.—S. J. G. writes: "What should be the size of a cesspit for twenty-four workmen's cottages to drain into? Would 14ft. by 12ft. by 6ft. deep be large enough?"

It is assumed that the rain- and storm-water is separately removed, and is not discharged into the cesspool. If the cesspool is intended to receive the whole of the foul drainage from the cottages—such as w.c.'s, sinks, &c.—then it should be about double the size mentioned, namely, 14ft. by 12ft. by 12ft. deep. On the other hand, if earth-closets are provided, then a cesspool 14ft. by 12ft. by 8ft. deep would be sufficiently large for the reception of fouled liquids from sinks, &c. T. E. C.

Strains in Ironwork.

HALTWHISTLE.—R. E. H. writes: "Where can I obtain Prof. Henry Adams's book on 'Strains in Ironwork,' and what is its price?"

The book is published by E. & F. N. Spon, Ltd., 125, Strand, W.C., price 5s.

Books on Architecture.

ELLISTOWN.—E. O. writes: "Kindly name a good illustrated book on architecture, showing a few good examples of each period."

We should think "The History and Description of the Styles of Architecture," by T. Talbot Bury (Crosby Lockwood & Son, 7, Stationers' Hall Court, E.C., price 2s.), would serve your purpose, but if you require a larger and more complete work get "Classic and Early Christian Architecture" by Prof. T. Roger Smith and John Slater, and "Gothic and Renaissance Architecture" by Prof. T. Roger Smith and Edward J. Poynter (Sampson Low, Marston & Co., Fetter Lane, E.C., price 5s. each).

Ancient Lights.

PLYMOUTH.—CONTRACTORS write: "What length of time must a window enjoy an uninterrupted view before it becomes an 'ancient light'? We are desirous of building stores on one side of our yard, on which abut two dwelling-houses which were built in June, 1887. We should not deprive the back rooms of these houses of their light to any great extent, but should prevent their overlooking our premises."

The period necessary to constitute right of light is twenty years, but as any obstruction must be in continuous existence for a whole year within these twenty years, the period is actually narrowed down to nineteen years and a day. You give us no definite particulars of the effect of the proposed building on the adjoining owner's light, but provided he obtains sufficient light for the carrying on of his business you can interrupt his view.

R. I. B. A.

PRIZES AND STUDENTSHIPS, 1902.

STONEHENGE.

A MEETING of the Royal Institute of British Architects was held last Monday evening, Mr. John Slater, vice president, occupying the chair. The hon. secretary, Mr. Alexander Graham, announced the decease of Mr. John Lee Hodgson, associate, who practised at Lille, France. The deed of awards in the Institute competitions was then read by the secretary, resulting as follows:—

Institute Silver Medal and 25 Guineas for Essays.—Not awarded. Mr. Geoffry Waddell, of Glasgow, was, however, awarded 10 guineas for his essay under motto "Serlio."

Institute Silver Medal and 10 Guineas for Measured Drawings.—Mr. Frederick W. C. Gregory ("Cavendo Tutus"). 5 guineas each were also awarded to Mr. R. Wynn Owen, A.R.I.B.A., of Liverpool ("Aidan"), Mr. Stanley Towse, of Catford ("Inca"), and Mr. Edwin F. Reynolds, of London ("H in circle").

Soane Medallion and £100.—Mr. James B. Fulton, of Glasgow ("Iona"). Medals of merit were also awarded to Mr. Lionel G. Detmar, of Sutton, Surrey ("Balneæ"), and Mr. Thomas Anderson Moodie, of Bayswater, W. ("Tepidarium"); and a certificate of hon. mention to Mr. Vincent Harris, of Regent's Park, N.W. ("Io.")

Owen Jones Studentship: Certificate and £100.—Mr. Edward H. Bennett. Ten guineas were also awarded to Mr. Percy E. Nobbs, of Chelsea, S.W., and five guineas to Mr. James McLachlan.

Pugin Studentship: Silver Medal and £40.—Mr. C. Wontner Smith, of Finchley, N. Five guineas each were also awarded to Mr. A. Muir and Mr. J. Myrtle Smith (of Stratford, E.); and a certificate of hon. mention to Mr. J. Harold Gibbons, of Manchester.

Godwin Bursary: Silver Medal and £40.—Mr. Charles A. Daubney.

Tite Prize: Certificate and £30.—Mr. Charles Gascoyne, of Nottingham ("Lion Heart"). A medal of merit was also awarded to Mr. Andrew Hutton ("In Memoriam"); and certificates of hon. mention to Mr. W. Curtis Green ("Marble"), Mr. Arthur R. Gough ("Rex" on grey strainers) and Mr. Cyril E. Power ("Shamrock").

Grissell Gold Medal and Ten Guineas.—Mr. Lionel M. Grace, of Steyning, Sussex ("Toby").

Asphitel Prize of books value £10 (for highest place in Examinations).—Mr. Charles Thomas Adshead, A.R.I.B.A., of Liverpool. A prize of books value £10 was also given to Mr. F. Dare Clapham, of Eltham, Kent, who obtained the highest number of marks on record in the Special Examination in June, and was not eligible for the prize.

Mr. Detmar J. Blow then read a paper on "The Architectural Discoveries of 1901 at Stonehenge," which was illustrated by a number of drawings and lantern slides. Mr. Blow described the excavations and the means of placing the largest leaning monolith into a vertical position to make it safe. This monolith had a decided entasis, and the semicircle of stones gradually rose in height to this one, which was the largest. The shape of these monoliths he thought might have been taken from flint implements, and the entasis suggested the origin of the column. Numerous flint instruments or tools were found beneath the stone, which had been used to work it, the larger evidently used as hammers to take off the greater roughness, and the smaller to dress it more carefully. A picture of Japanese workmen dressing similar stones by these means was shown. The large stones were of Sarsen and the smaller implements of a blue stone.

Sir Norman Lockyer, in opening the discussion, referred to the investigations he and Mr. F. C. Penrose had recently made with regard to the orientation of Stonehenge, which were described in a paper published by the Royal Society. From the evidences he thought they were justified in assuming that the Sarsen stones were erected in the Neolithic age—that was to say, before bronze was in use for ordinary work in this part of England. He and Mr. Penrose had been working for some time from a different point of view to other archæologists, in endeavouring to find the date of Stonehenge and similar monuments from their orientation. Stonehenge lent itself best to work with the theodolite, as it was not surrounded by mountains, the horizon being clear, and it was in a fair state of preservation. It was therefore selected for the experiment. In Egypt and Greece they had had a comparatively easy task, from the fact that the temples there were orientated to particular stars which changed their position very materially in a few hundred years, but Stonehenge had not been turned to the stars; people had, however, gone there from time immemorial to see the sun rise on the longest day, and it seemed certain that it had been planned for this. There was a very slight difference, which had been increasing for thousands of years, between the plane of the ecliptic and the plane of the equator, this angle being known as the obliquity of the ecliptic. Working on this they came to the conclusion that the approximate date of the erection of Stonehenge was 1680 B.C., which, however, could not be determined nearer than 200 years. The people who built these early monuments had been very much misrepresented by those who did not know what they were driving at. These early poor people, unless they found out the time of year for themselves, had absolutely no means of knowing when their agricultural pursuits were to be done, and these erections served the purpose of a calendar. At the very first blush of civilization, therefore, we found these temples. In Egypt, for instance, the first inhabitants determined the time of Easter, then the race that built the Pyramids determined the autumnal equinox, and at the time of the erection of the Temple of Thebes the inhabitants worshipped the Solstice, or midsummer, as did those at Stonehenge. Thus, first they determined the month of May, then August, and, lastly, the longest day.

Mr. F. C. Penrose said his and Sir Norman Lockyer's attention had been first called to the subject by noticing that the avenue at Stonehenge was exactly similar to the avenues of sphinxes in front of the Egyptian Temples. Mr. Gowland had estimated from the state of the flint implements found at Stonehenge that it dated from 2000 B.C., which approximately agreed with the date obtained from astronomical determination.

Mr. Emanuel Green suggested that the thirty stones at Stonehenge were used to determine the days of the month; and there was a thirty-first stone which would probably have been used for the five extra days. The stone used in the monuments was obtained on the ground in the form of large boulders which had been deposited by some geological means.

Mr. W. H. St. John Hope having spoken, Mr. Penrose stated that he thought Stonehenge was in all probability roofed in by means of beams laid flat.

On the motion of Mr. Slater a vote of thanks was accorded Mr. Blow, who, in reply, said he agreed in thinking Stonehenge was roofed in as, the outer circle of stones being lower, they would allow the water to be carried off. From the fact that everywhere inside the monument worked stones were found he gathered the whole place must have been used as a masons' yard. If the upright monoliths had been put in position by digging a sloping pit and sliding them down, a large mound would have been left in the centre from which baulks of timber could have been laid on to the uprights and the lintels rolled up on to them.

The American Office Building for the Strand, proposed to be erected on the site between the new Gaiety Theatre and the Law Courts, will not be built just yet, as the special committee of the London County Council to whom the matter was referred have refused a grant of 999 years lease, though they have expressed their willingness to negotiate with the syndicate on the basis of a 99 years lease; it is believed, however, that such a short lease would not meet the requirements of the syndicate.

BUILDING CONSTRUCTION.

(*Continued from p. 373, No. 361.*)

73. SINCE writing the previous article I have consulted Mr. John Emerson as to the details of slating from the workman's point of view. The bench, or "banker," is formed of whatever can be had; a rough box to carry the straight-edge over which the edge of the slate is laid to dress it to a straight line, and a sufficiently strong framework of slater's battens, on which the slate rests so that it does not need to be held up by hand. The slate should lie with a fall to the straight-edge so as to bear upon its corner. A common form of straight-edge is that shown at Fig. 101 (see previous article). It is a heavy iron dog supported as shown. The dressed corner of a piece of fairly hard stone or slate answers very well for a dressing edge. The dresser should observe whether there is any bend or camber in the slate; such a slate, if fit to be put into work, should lie *convex* up, and it may need to be redressed with this intention. The dresser's square should be a wooden T-square; an L-square is not so suitable, because the T-square lies better balanced on the slate, and it does not need to be turned for the second corner. The distance of the holes from the tail is marked on the blade of the square, and the length of the slate is also marked upon it. The dresser sees at once if a slate is too long or too short. He marks with the pick of his zax what dressing is to be done, and also marks the positions of the holes. It is good for the dresser to remember, when he has slates of different sizes marked upon the blade of his square, that the holing distance differs by half the amount of the difference of length; for example, for a slate 20in. long and for 3½in. lap the holing distance from the tail is 11¾in., and for a slate 26in. long the holing distance is 14¾in. When the slating is to be rendered it is useful to dress off about ¼in. from A to B (Fig. 108). This leaves an opening here between the slates into which the rendering squeezes, thereby obtaining a "key." There is a strong temptation to hole the slates with the pick of the zax, but this should not be allowed; they should be holed with the screw-punch shown at Fig. 107. The action of this tool is obvious. Fig. 108 shows how the tool is made use of; four pieces of slater's battens are nailed together as shown, and they and the tool are fixed to a box or bench. If one punch is used each slate has to be turned for the second hole; with two punches the slate only needs to be moved a short distance parallel to its first position to bring it under the second punch. A pair of labourers can hole slates with great rapidity in this way. It would appear that this arrangement makes marking the holes by the dresser unnecessary, but the marking involves little loss of time; and if the holing is done by labourers the marking is a check in the event of error or displacement in the frame. The hammer called a slater's hammer is shown at Fig. 109; it is a useful tool for repair work. In holing slates with the pick of the zax or of the slater's hammer it should be seen that the slate does not flake too much before the point. Remember that slates are cut by driving a row of holes on the line of division. A good plan is to do such holing not on an edge but with the slate laid upon a piece of wood—end wood is best—but often it is convenient to use the top of a rafter or a batten over a rafter. Many of the medium-sized slates now on the market are much too thin. The "quality" assigned to slates by quarrymen should not blind us as to what is best for the work. Workmen go up on roofs to do repairs and for various purposes; slates should be strong enough to bear somewhat rough treatment of this kind; and what quarrymen call "first quality" is not always the best quality for work.

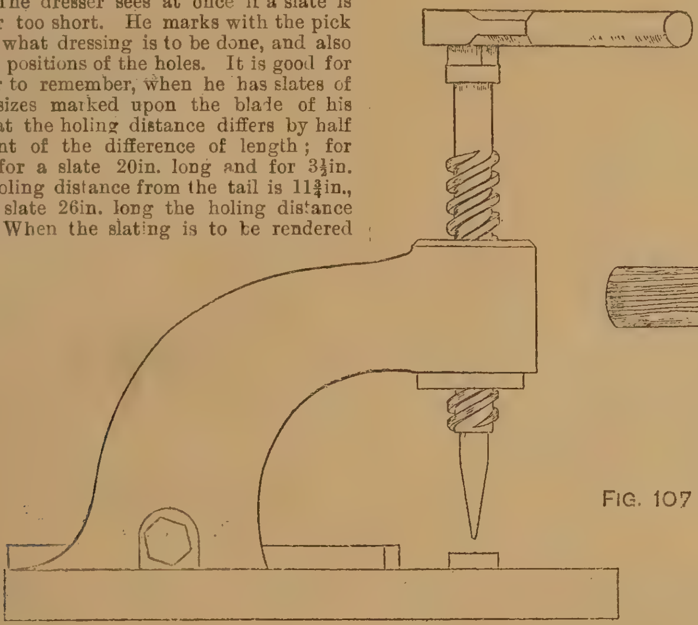


FIG. 107

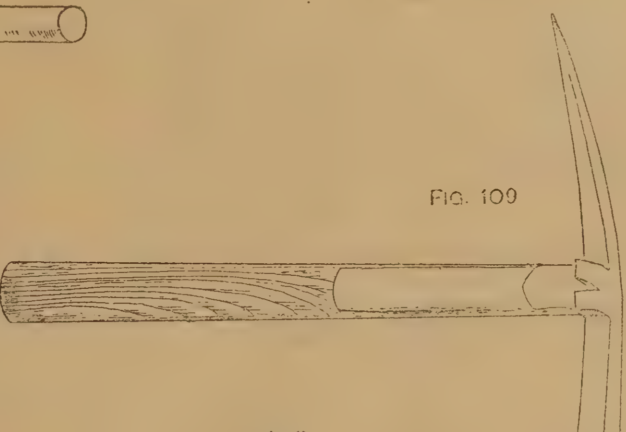

FIG. 109

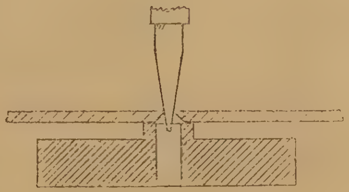


The attention of students is directed to what is called the "grain" of a slate. It is not intended to deal here with the subject of slaty cleavage. The student may consult books of geology about it. If a piece of slate has two planes of cleavage nearly at right angles, it may easily divide into a bundle of slate pencils; this, however, is the extreme case. What is called the "grain" of a slate is its tendency to split lengthwise. This grain should always be the long way of a slate, because an up-and-down crack is a much less serious thing than a crack across. For under-eaves it might be thought convenient, as preventing waste, to use slates of the breadth required laid with the grain horizontal, but this should not be allowed.

In covering with slates of a definite size it is easy to keep the "perpends" right—that is, to have joints which break truly in line from ridge to eave; but it will be found that slaters, left to themselves, pay little attention to this refinement. They should attend to it, however.

Terms.—Head, top of slates as fixed; *tail*, bottom edge; *back*, upper surface; *margin* or *weather*, that part of a slate which is exposed to the weather; *lap*, the bond of three thicknesses of slate—it may be taken to be the distance from a nail-hole to the tail of the slate next above the nail-hole; *gauge*, the distance from the nail-hole to the head—it is also the breadth of the margin or weather; *bond* is suggested by comparing the appearance of slating to brickwork or ashlar, the bond being true when in all cases a joint meets the tail of a covering slate in the centre of its length: this particularly assumes slates of equal breadth having the perpends right.

Fig. 110 shows the arrangement for slating the cottages. It shows clearly a simple form of scaffold for these houses (of low height). The scaffold reaches to within about 2ft. of the eave. The bottom eave (doubling eaves-course) is laid on the tilting fillet, bedded on the beam filling, and nailed by the head to the first batten. The work is carried up as far as the slater can conveniently reach from the scaffold; he proceeds further by means of a ledger resting on creepies, which are made fast by light ropes to the ridge —or over the ridge.

Each slate covers an area equal to that of its margin or weather. For slates 20in. by 10in. and a 3½in. lap, this is 8¼in. × 10in. = 82·5 sq. in. A square of slating is 100 × 144 = 14,400 sq. in. It will therefore take about 175 slates to cover one square. This is on the supposition that it is all uniform slating; but allowance must be made for waste (*a*) owing to the doubling eaves-course; if we could imagine this course to be an ordinary course, from which the margins are cut off and reserved for the ridge, and that the length of the rafter suited the lap, there need be very little allowance on this score; (*b*) cutting for valleys, chimneys, &c.; and (*c*) an allowance for breakages and defective slates.

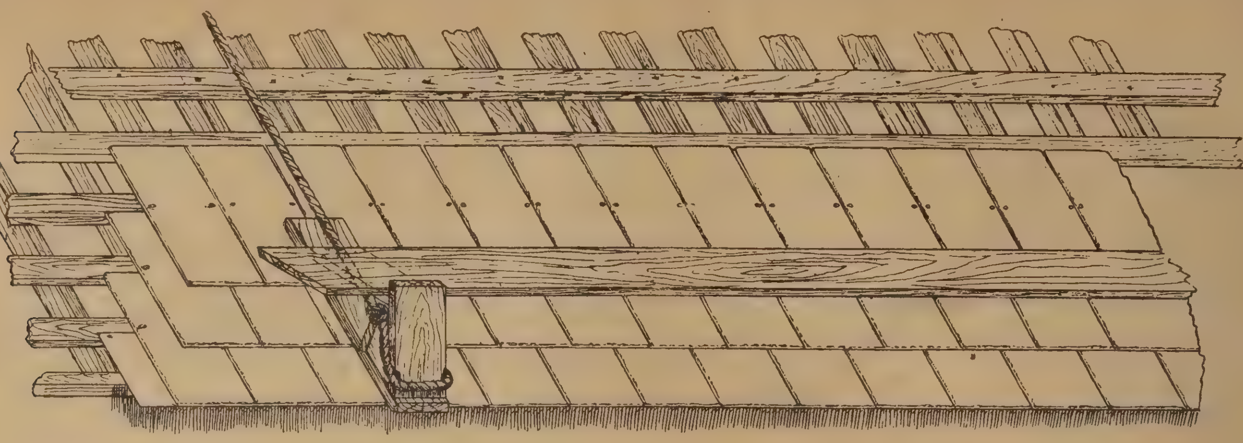
Plasterer.

74. The coarse stuff for plaster should be prepared as already described for making mortar for masonry where the lime is run to putty, except that more care must be taken in running the putty. The thickness of sand on the floor should be much less. For these houses we shall suppose that the lime is slaked in tubs, and that the milk is lifted in buckets and passed through a ⅜in.-mesh riddle placed on a stand (which may be rocked) at one corner of the floor. The sand forming the floor should be carefully screened before being put in position. The putty thus formed is of different qualities; that immediately below the riddle is coarser in grain. The very fine suspended particles of lime are carried away to the remote margin, and it is from this region the plasterer gets his putty for setting stuff.

To make coarse stuff: when the putty is cool add cowhair procured from a tannery, say about 1lb. of hair to a cub. ft. of putty. The hair should be long and clean, and free from grease. It is beaten with laths and thus opened out; it is mixed evenly through the putty by means of an iron rake; the haired putty and the complement of sand are now tossed, partially wetted, and let stand for two or three weeks to sour. Care should be taken that the sand is not sea-sand, because this, owing to the minute quantity of salt attached to each grain, takes moisture from the air and maintains the plaster of which it is a constituent in a damp condition. The mortar is tempered as already described.

The collars and rafters are to be lathed with *lath-and-half* laths, fastened with cut nails. Care is to be taken to allow sufficient space between the laths for the coarse stuff to squeeze through and bend over to form a "key."

The lathed work and the walls are now to be rendered (first or scratch-coated). A scaffold is put up to command the whole of the ceiling, the mortar-board is placed on a light cask about the centre, and the attendants must keep a constant supply of tempered coarse stuff on the mortar-board. The plasterer tries the stuff on the board with his trowel, takes up some on his hawk, and transfers it from the hawk to the lathing with his trowel, following the trowel with the hawk to receive any stuff that may fall away. The plasterer must not work his trowel across the laths in laying this first coat; such a mode would destroy connection between the



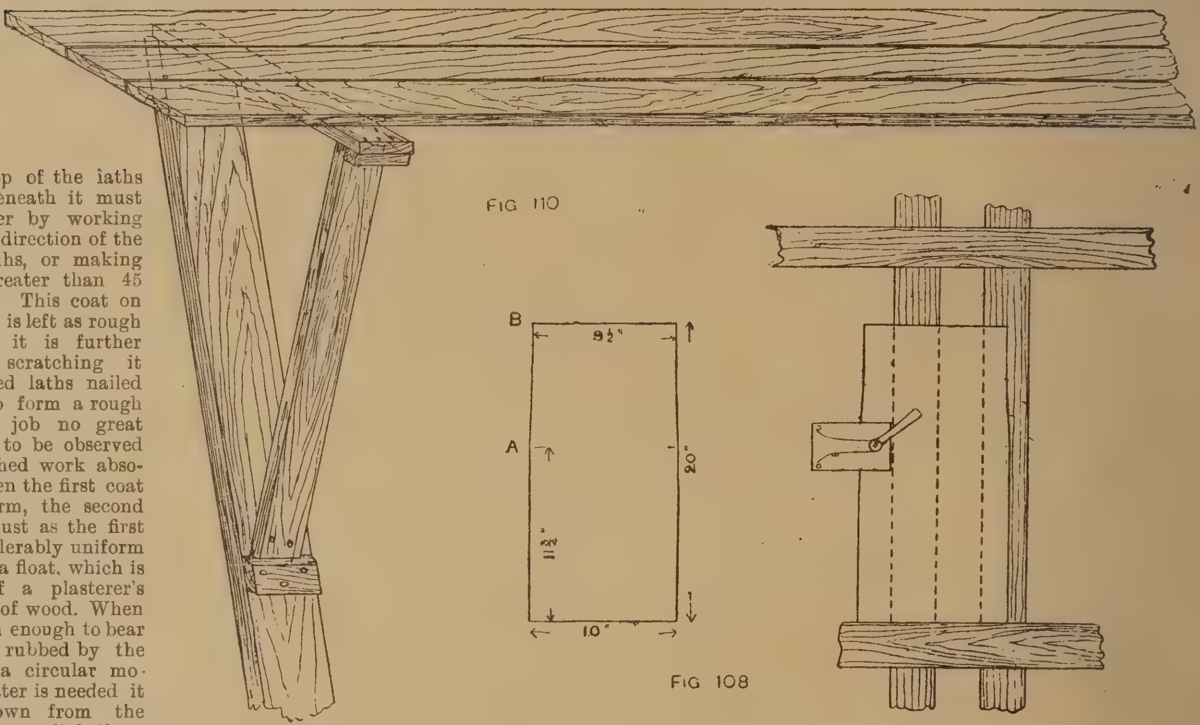


FIG 110

FIG 108

"keying" on top of the laths and the plaster beneath it must be laid on either by working the trowel in the direction of the length of the laths, or making an angle not greater than 45 degs. with them. This coat on lathing and walls is left as rough as possible, and it is further roughened by scratching it with some pointed laths nailed together so as to form a rough comb. For this job no great nicety will have to be observed to have the finished work absolutely true. When the first coat is sufficiently firm, the second coat is applied—just as the first coat was laid, tolerably uniform and floated with a float, which is of the shape of a plasterer's trowel, but made of wood. When the plaster is firm enough to bear it, its surface is rubbed by the float (giving it a circular motion); and if water is needed it is applied, thrown from the points of a brush, small hollows being filled by the application of small quantities of plaster. When the floating is sufficiently firm the surface is set with the fine part of the putty applied by the trowel and spread over the floated surface as thinly as possible; it is then trowelled, then wetted, and finished with a brush.

The outside walls are to be rough-casted. Mortar is prepared as for coarse stuff, except that no hair is added to it; it is applied with the trowel and hawk as for rendering, and this coat is rough-floated. It should be left as rough as possible; it is advisable to roughen it by means of a float with some small nails in its working face. The rough-cast is next applied. Some thin mortar rich in lime is made with sand and putty, and to this is added gravel of the proper coarseness for the rough-cast; it is easy to judge by trial when the proper proportions are attained. The rough-cast is applied by taking it up on small wooden spade-shaped tools and throwing it from these against the prepared walls. The slating at the eaves and reveals of windows, doors, &c., must be protected with bags or pieces of canvas, &c., from the stray splashing of the rough-cast. It is most important that the sand and gravel used for rough-cast shall be absolutely free from clay, as frost would, in the case of clay being mixed with the sand or gravel, destroy the work.

Ironwork.

75. The drawings show the eaves-gutters supported on iron hooks driven into the wall. In brickwork we can always find a joint into which a hook may be driven. It is a little more difficult where the wall is rubble-masonry. A hook should be driven as close to the socket of the eaves-gutter as possible. Suppose we are dealing with the single cottage (Fig. 81), and that we wish to utilize the roof-water. The gutter has a metal end at the left-hand end of frontage, and it falls, say, ¾-in. to the right-hand end. We can afford another ¾in. fall across the gable, and a little more than ½in. further fall will bring us to the shed near the back door. Here there will be a second dead-end and a piece with a hole for a swan-neck which discharges into a hopper over a down-spout, which discharges through a shoe into a barrel, which may be one of several set upon a rough stand and connected near the bottom with pieces of galvanized-iron pipe. (If any potable use is likely to be made of rainwater it should not, if possible, lie in lead. No doubt we have provided a lead valley and lead flashings, but owing to the short time the water is in contact with them they probably do but little harm; nevertheless they are objectionable. Spring water containing earthy salts does not combine with lead.) Water is drawn from the casks by a cock, which must be a good-fitting one, because a very small leakage is serious in such an arrangement. These eaves-gutters may be 4in. half-round, and the down-spouting 3in.; the piece across the pigstye-eave will discharge by a swan-neck into one length of down-spout furnished with a shoe delivering on the ground at the outer end. The gutters, &c., shall be jointed with a mixture of white and red leads, and fastened with screws; the hooks shall be of ½in. iron, and they shall have sufficient wall-hold. The piggery gate shall be strongly made; the cross-rails shouldered to the heel-post, and well riveted to both heel-post and striking bar. It shall be properly hung, turning on an iron socket let into the sill, and held at the top by a good strong strap-eye, well secured, built in with cement in the piggery wall; it shall have a proper running bolt to run into a sufficient eye made in a good-sized stone set there for the purpose. It shall open inwards, and it shall have a sufficient iron stop to prevent it opening outwards; the gate shall be properly proportioned, and it shall weigh 70lbs.

In the kitchen shall be provided and properly fixed a grate suitable for an open fire of wood or turf with oven No. , page S.'s catalogue, list price £1 10s., or from a different maker equally as good as that quoted. The bedrooms shall be fitted each with a mantel-grate No. , page , S.'s catalogue, list price 12s. These grates shall be properly set and fixed, having firebrick settings properly laid in fireclay. The jambs of the kitchen fireplace shall be finished in cement-plaster neatly worked to the general plaster of the breast.

Glazier.

76. The common window-glass now in use is sheet glass, which is to be had of various thicknesses and qualities; 15oz. glass averages 15oz. in weight per super. ft. The glazier lifts a sheet of glass out from a crate of sheets; taking hold of it by the top edge in both hands, he rests it on its bottom edge on the table and lowers it flat, supporting it with a hand in the middle as he does so. He decides how he shall cut up the sheet to get the special size of panes out of it with least waste; his tools are (*a*) a cutting diamond, (*b*) a light flexible straight-edge of wood, (*c*) a wooden T-square

with long thin blade, (*d*) a large pliers, (*e*) a puttying knife. Let not the ordinary individual who has never tried it before think that, given a glazier's diamond and straight-edge, he can cut glass. For most diamonds there is only one position in which it must be held to make a good cut. The glazier sets it in this position by habit and use, and he knows from the sound he makes as he draws it along the glass, pressing gently against the straight-edge, whether he is "cutting" or merely "scoring" the glass; he keeps his hand in the same position during the whole length of the cut. He marks the sheet into breadths with a small piece of dry soap; he cuts it up to these breadths in succession, and using his T-square and a standard length he divides the strips of glass into panes of the proper size. Usually he cuts clean and safely, but he may need his pliers to take off a too sharp corner or to take hold of a very thin paring. The glazier's cut must not be too complete; the pieces are separated with some little strain, allowing the piece he is taking off to hang over the front edge of his table. A cut that is too complete may run faster than the diamond and result in the destruction of the sheet.

Glazier's putty is made from whiting and linseed oil, either boiled or raw. Sometimes the putty is mixed with red lead, and such putty becomes very hard in time, so that it is not easy to remove it when it is necessary to do so to fix a new pane. When raw oil putty is painted over it is a very long time before it gets hard. Boiled oil putty gets hard sooner. Raw oil putty is not so nice to handle and work as boiled oil putty. As a rule, glaziers do not now mix the putty they use; they buy it made up in casks ready mixed. The operation of glazing common sashes is exceedingly simple. The sashes are first primed, and when the paint is dry some putty is placed along the rebate of the sash round the openings for the panes by the glazier, using either his thumb or his putty knife for this work; the panes are pressed into this, called the bedding; they are next tacked in place; then the sash is top-puttied, the glazier using a puttying knife, holding some putty always in the palm of his left hand; the sash is now set up, with the bedding side turned to the glazier, who cuts off the surplus putty, makes up any deficiencies, and smoothes off the surface. The sash is now lightly brushed with a duster and set aside as glazed.

There remains painting and plumbing; but it is advisable to deal with these trades in connection with larger houses.

(*To be continued.*)

Surveying and Sanitary Notes.

A Lady Sanitary Inspector for the City.—The City Corporation has decided to appoint a female sanitary inspector. Applications for the post, the remuneration of which commences at £125 and rises to £150, are invited, and must be delivered at the Guildhall not later than Saturday, February 1st.

Fleet Street Widening. — With the sale by Messrs. Douglas, Young & Co., on January 22nd, of the corner site adjoining the "Old Bell" in Fleet Street, the important improvement at this end of the thoroughfare will be completed.

The View from Richmond Hill. — Mr. Max Waechter, Deputy-Lieutenant of Surrey, who recently bought and presented Petersham Ait to the Richmond Corporation, has purchased Petersham Lodge, lying just beyond Petersham Meadows, towards preserving the view from Richmond Hill. This estate was recently offered to the Richmond Town Council for £10,000.

Mr. Richard William Griffiths died on January 10th at 120, Melfort Road, Thornton Heath, Surrey, and was buried on Wednesday last at Highgate Cemetery. Deceased, who was in his seventy-second year, practised as a quantity surveyor for nearly fifty years in various parts of London, latterly under the style of R. W. Griffiths & Son, at 22, Henrietta Street, W.C. The business will be continued under this title by his son, Mr. Owen Griffiths.

Masters and Men.

Wages in the Building Trade in 1901 are stated by the Board of Trade to have experienced a further rise, but only about half as great as in 1900. Nearly 30,000 operatives received advances, and 6,614 (most of whom are in Scotland) sustained decreases, the computed nett increase in the average weekly wages of the workpeople affected being 1s. 3¼d. per head.

The Bradford Dispute which has been proceeding between the master-masons and their operatives was brought to a settlement last week after a cessation of work which has lasted since May 1st of last year—eight-and-a-half months. The masons have resumed work at a reduction of wages of ½d. per hour, and agree to work peaceably with non-unionists, while the masters withdraw a demand for a change in the dates on which notices of alterations in the conditions of work should be given.

New Patents.

These patents are open to opposition until February 24th.

1900.—**Purifying Air.**—23,435. W. Key, 109, Hope Street, Glasgow. A solution of barium hydrate or peroxide of iron is allowed to trickle down screens or rods, in combination with hydrated oxide of lime, and the air is forced or drawn through by a fan: the object being to extract carbonic acid, sulphuretted hydrogen, ammonia, dust and other organic matter in the air.

1901.—**Tramway Paving Blocks.**—3,620. H. Melsom, 121, Colmore Row, Birmingham. In order to form a water-tight joint and prevent the rail corroding, bituminous cloth is put between the rail and the paving blocks; moreover, the rail is bedded on bituminous cloth. Wedge-shaped blocks with similar cloth joints are provided outside those adjacent to the rail, the object being to facilitate removal.

Venetian Blinds.—13,773. W. H. Douglas, 2, St. Bee's Street, Denmark Road, Greenheys, Manchester. The blind can be used either as a short one for the lower portion of the window, or for the whole of the window—this by means of two sets of cords working over pulleys in a top rail.

Hollow Bricks.—22,827. D. W. Anderson 526, South Laurel Street, Richmond, Henrico, Virginia, U.S.A. The brick is pierced throughout its length with three holes or passages and carries on its outer face a ribbed tile, which is plastered. When built in position, the passages are continuous throughout the walls and may be used for heating or cooling the apartment they enclose.

The following specifications were published on Saturday last, and are open to opposition until February 31st. A summary of the more important of them will be given next week.

1900.—19,571, Spooner, machinery for making sawdust, shavings, &c., into fuel. 23,412, Cameron, Commin & Martin, apparatus for purifying sewage. 23,627, Jennings, circular pocket slide-rule for timber. 23,676, Regnander, apparatus for transporting, elevating and piling lumber. 23,851, Diesler, manufacture of cement.

1901.—558, J. Duckett & Son, Ltd., Duckett, Button & Bullock, top-flushed slop-water closets. 1,833, O'Brien, disinfectant flushing cisterns. 2,700, Gibbons, panic bolts for doors. 3,272, Ashton soil-pipes. 3,351, Shanks, water-closets and cisterns. 3,352, Shanks, fittings for lavatories, baths, &c. 3,954, Wintle, fastening device for hand tools. 4,074, Hamblett, self-locking hingeless door. 4,124, Mackay, cocks and taps. 5,257, Jacquart & Booraem, brick- or tile-coverings for beams. 8,700, Taylor & Kersett, fastenings for the doors of cold stores. 23,636, Reck, radiators for heating. 23,981, Wellington, street lamp-posts. 24,345, Horton, street door bells. 24,376, White & White, syphon-flushing cisterns and wash-out closets.

Engineering Notes.

Mr. Robert George Young, M.I.C.E., resident engineer at the London County Asylum, Colney Hatch, died recently at the age of 53 years.

Municipal Tramways for Wigan.—The Wigan Corporation have agreed to purchase the Wigan Tramways Company. The price is £45,000. The Corporation proposed to work the lines by electricity, in conjunction with the existing system.

At the Drury Lane Pantomime the elaborate electrical effects in the great fan scene are installed on the E.L.B. system. Several thousand lamps are used nightly. The same system of the Electric Lighting Boards Company has also been applied for Mr. Moss's large "Cinderella" pantomime at Liverpool.

Engineering Standards Committee.—The Lords Commissioners of the Admiralty have nominated Mr. W. E. Smith, chief constructor, as their representative on the Engineering Standards Committee, and the Marine Department of the Board of Trade is to be represented on the same committee by Mr. Peter Samson, Engineer-Surveyor-in-Chief.

American Workshop Methods: Why they Succeed.—At a meeting of the Institution of Civil Engineers held on January 14th (Mr. Charles Hawksley, president, in the chair) a paper was read on "American Workshop Methods in Steel Construction" by H. B. Molesworth, M.I.C.E., in the course of which he referred to the bridge shop at the Pencoyd Works of the American Bridge Co., near Philadelphia, which is electrically driven, each of the cranes and larger machines having an independent motor. The drawings are prepared in a very complete manner and give much more information than is usually furnished on drawings in England. Great care is taken to minimize smith's work, and to duplicate as many parts as possible. Mr. Molesworth said that the causes of cheap working in America might be summed up as follows:—(1) The workmen, though more highly paid than in England, turned out a much larger quantity of work. (2) The arrangement of the works was more carefully thought out, and labour-saving appliances were more used. (3) There was more method, and probably more scientific knowledge, in the drawing-office. (4) The works were run night and day. (5) The templating was reduced to a minimum by care in the drawing-office and by the use of automatic machinery and stops and guides. (6) Obsolete machinery was turned out of the works as soon as it was superseded by anything better. (7) All tools were kept in a state of perfect efficiency. (8) Railway freights were lower than in England.

Explosions in Electric Street-Boxes. — On Wednesday last at the Guildhall Mr. A. C. Trotter held at enquiry on behalf of the Board of Trade into the explosions which occurred on January 4th and 5th last in the electric street-boxes at King Edward Street and Newgate Street. Mr. W. H. Catchell, engineer-in-chief to the Charing Cross and Strand Electricity Supply Corporation, said that a man went down the manhole to investigate a defect, but found the air so stifling that he had to leave hurriedly. In the western districts the company worked with ventilated conduits, so that if there was an escape or overcharge of bitumen gas it could be confined to where it occurred, but different conditions prevailed in the area in question. The first explosion was the result of the lowering of a lighted lamp, which exploded the bitumen gas; and the second resulted from the lighting of a match by an employee when he thought all was clear. Mr. Catchell said he did not think any better system than the present could be adopted by his company to prevent explosions. There was no regulation of the Board of Trade providing for special ventilation of the street-boxes. The explosion in the street-box of the City of London Electric Lighting Co. was then enquired into, and the engineer of the company gave it as his opinion that the explosion was probably due to increased heat in the temperature affecting the tubing, as certain parts of it showed signs of having been heated. He suggested as a possible preventative of explosions the metallic covering-in of the wires. Other technical evidence having been given, the enquiry closed.

FIRE-RESISTING BUILDINGS.

The Associated Fire Offices' New Specifications.

As briefly announced in our last issue, in order to encourage the construction of buildings of better fire-resisting character than most of those ordinarily classed as "fireproof," the Associated Fire Offices have drawn up two new specifications: one for buildings occupied as cotton-mills or woollen-mills, or buildings for similar textile trades; the other for ordinary buildings, as sale-shops, warehouses and factories other than cotton-mills, &c. It is intimated that the Fire Offices will make reductions in rates for buildings which conform to these specifications.

I.—The following specification is applicable only to buildings occupied as cotton-mills or woollen-mills or to buildings used for similar textile trades:—

Height and Area.

1. Height not to exceed four storeys and cellar. The ceiling of the cellar not to be more than 3ft. above the lowest point of the land level or ground line of the site on which the building stands.

2. Superficial area of any one compartment not to exceed 25,000 sq. ft. internal measurement, excluding area of window recesses and doorways.

> *N.B.—The height of any compartment, excluding cellar, to be not less than 12ft., measuring from the floor level to the highest point of the ceiling.*

External, Party and Internal Walls and Partitions.

3. Brick, terra-cotta or cement-concrete composed of broken brick, burnt ballast, furnace slag, clinker, or other similar hard and burnt material.

4. No external or party or division wall to be less than 13in. thick in any part, or if of concrete 20in.

> *N.B.—Stone used externally only as ashlaring or facing, with a backing of brickwork not less than 13in. thick, and for dressings, sills, string-courses and cornices, allowed.*

5. All internal partitions to be of incombustible material, excepting only office enclosures of hard non-resinous wood with or without glazing.

6. If there is any building adjoining, the dividing or party wall to extend at least 3ft. above the roof of the fire-resisting building.

Flues.

7. All flues to be built of brickwork, no part of which towards the interior of the building is to be less than 9in. thick, and all furnace flues to be lined with firebrick throughout for a distance of at least 20ft. from the furnace. No timber or woodwork to rest in or be plugged into the brickwork of any flue.

Openings in External Walls.

8. The total area of openings in the external wall of any storey not to exceed one-half of the area of the wall (measured as to height from floor to ceiling of the storey in which the openings occur). All loop-hole or teagle doors and frames and window-frames and sashes to be of iron or other hard metal.

9. Every window or other opening opposing (whether directly or diagonally) and within 20ft. of any window, skylight or glazed or other opening in any other building (whether such latter window, skylight or opening be protected or not), or overlooking (whether directly or diagonally) and within 20ft. of the non-fireproof roof of any building, to be protected by "fireproof" shutters or "fireproof" doors which are automatically self-closing in case of fire.

Floors.

10. Brick arches, terra-cotta, fireclay, or concrete as above described, the floor being in no part less than 6in. in thickness, and carried on metal joists, girders and columns or brick walls or piers.

> *N.B.—Floors of wood not less than 9in. thick, ceiled with plaster or metal lathing, and with the floor boards laid on the bearers without intervening space, allowed.*

11. Wooden flooring laid on brick arches, terra-cotta, fireclay, or concrete as above described allowed, provided there is no intervening space. Wooden fillets not exceeding 3in. deep permitted if laid on brick arches, terra-cotta, fireclay, or concrete as above described, the intervening spaces being filled with incombustible material.

11A. Scuppers to carry off water, the opening of each of which shall not be less in area than 21in. super., to be provided in the external walls to each floor at intervals of not more than 25ft.

Roofs.

12. Roofs to be entirely of the incombustible materials as described for floors in Rule 10, except that 4in. be substituted for 6in. thick, but there may be erected above them light shelters or roofs constructed entirely of incombustible materials.

> NOTE.—*Glass not less than ¼in. thick in sections, not exceeding 36in. super., and wired glass not exceeding 1in. mesh, in sections not exceeding 144in. super., in either case set in metal, shall for the purpose of this rule be deemed incombustible. Outlets on to roofs rendered necessary to satisfy the requirements of the Factories and Workshops Act permitted, provided that all doors and frames be of iron or cased in iron plate at least ⅛in. thick, and that they be self-closing.*

Protection of Structural Metal Work.

13. All columns or stanchions to be covered with brickwork or porous terra-cotta (at least 2in. thick), or with cement, concrete, or plaster at least 1½in. thick, keyed into metal supports and protected by a metal guard up to a height of not less than 4ft. from the floor where cement, concrete or plaster only used.

14. Girders, joists, lintels, and all structural metal work (other than columns and stanchions, but including framework of roofs), where not covered with brickwork, to be completely encased in porous terra-cotta at least 2in. thick, securely anchored, or cement, concrete or plaster at least 1in. thick keyed into metal supports.

15. Space must be left at the ends of girders and joists to permit of expansion.

Linings and Ceilings.

16. No lining of wood or textile fabric to any part of the walls, partitions, ceilings or roof.

Floor Openings.

17. No openings through any floors allowed except holes to admit steam, gas and water pipes, and iron or earthenware tubes for electric conductors. All pipes and tubes to be cemented round the full thickness of the floor.

> *N.B.—All staircases, hoists, rope and strap races, and gearing-towers to be external to the four walls of the building and constructed entirely of brick or cement-concrete, as above described, at least 9in. thick.*

Hoists must be constructed in the staircase enclosures, and no opening thereto to be less than 6ft. from any opening into the building. Excepting hoists, the enclosing walls must be carried through and 18in. above the roof of the building, and the roofs, stairs and landings of said enclosures must be constructed of incombustible material. No openings permitted between the building and the rope and strap races and gearing-towers, and each opening from the staircase into the building to be protected by a "fireproof" door.

Shafting through Walls.

18. Shafting where passing through walls to fit closely into wall, or have wall-boxes closed with iron-plates not less than ¼in. thick, leaving no open space.

Pipes and Electric Conductors.

19. All pipes in the building, except water-pipes not exceeding 1½in. in diameter, to be of hard metal. No wooden casing to be used for enclosing electric conductors.

Communicating Compartments.

20. Two or more compartments each constructed in accordance with these Rules may communicate, whether by double "fireproof" doors or otherwise, provided that their aggregate superficial area does not exceed 25,000 sq. ft.

21. Two or more such compartments, whose aggregate superficial area exceeds 25,000 sq. ft., can only be allowed to communicate across a fireproof compartment, built up from the basement with walls of solid brickwork, and constructed in all other respects in accordance with these Rules, so far as the same are applicable, and having all openings protected by "fireproof" doors at least 6ft. apart.

22. Except as above, no communication allowed between a compartment constructed in accordance with these Rules and any other compartment.

II.—The following specification is applicable to ordinary buildings, such as sale-shops, warehouses and factories, excluding cotton-mills and buildings occupied for similar textile trades:—

Height and Cubical Contents.

1. Height not to exceed 80ft., measured from the lowest point of the land-level or ground-line of the site on which the building stands to the level of the highest part of the roof.

2. Cubical contents of any one compartment not to exceed 60,000 cub. ft.

> *N.B.—In computing cubical contents the whole surface, area, including half of the party-walls and the whole of the external walls, and the actual height from the surface of the lowest floor, are to be measured.*

Walls and Partitions.

3. Brick, terra-cotta or cement-concrete composed of broken brick, burnt ballast, furnace slag, clinker, or other similar hard and burnt material.

4. No external area or party-wall to be less than 13in. thick in any part, or, if of concrete, 20in.

> *N.B.—Stone used externally only as ashlaring or facing, with a backing of brickwork not less than 13in. thick, and for dressings, sills, string-courses and cornices, allowed.*

5. All internal partitions to be of incombustible material, excepting only office enclosures of hard non-resinous wood with or without glazing.

6. If there is any building adjoining, the dividing or party-wall to extend at least 3ft. above the roof of the fire-resisting building.

Flues.

7. All flues to be built of brickwork, no part of which towards the interior of the building is to be less than 9in. thick, and all furnace flues to be lined with firebrick throughout for a distance of at least 20ft. from the furnace. No timber or woodwork to rest in or be plugged into the brickwork of any flue.

Openings in Walls.

8. The total superficial area of openings in each external or area wall of any storey above the ground storey not to exceed one-half of the area of the wall (measured as to height from floor to ceiling of the storey in which the openings occur). All loop-hole or teagle doors and frames and window frames and sashes to be of iron or other hard metal. All windows above the ground storey to be glazed with glass not less than ¼in. thick, in sections not larger than 2ft. super., or wired glass not exceeding 1in. mesh in sections not larger than 4ft. super.

9. Every window or other opening above the ground storey opposing (whether directly or diagonally) and within 20ft. of any window, skylight, or glazed or other opening in any other building (whether such latter window, skylight or opening be protected or not), or overlooking (whether directly or diagonally) and within 20ft. of the roof of any building, to be protected by "fireproof" shutters or "fireproof" doors.

Floors.

10. Brick, arches, terra-cotta, fireclay, or concrete as above described, the floor being in no part less than 6in. in thickness, and carried on metal joists, girders and columns, or brick walls or piers.

> *N.B.—Floors of wood not less than 9in. thick, ceiled with plaster on metal lathing, and with the floor boards laid on the bearers without intervening space, allowed.*

11. Wooden flooring laid on concrete allowed, provided there is no space between the wood and the concrete. Wooden fillets not exceeding 2in. deep permitted if bedded flush in the concrete.

12. Scuppers to carry off water, the opening of each of which shall not be less in area than 21in. super., to be provided in the external walls

to each floor above the ground storey at intervals of not more than 12ft.

N.B.—In buildings within the City of London or within the area controlled by the London County Council, scuppers are not essential.

Roofs.

13. Roofs to be entirely of the incombustible materials as described for floors in Rule 10, except that 4in. be substituted for 6in. in thickness.

NOTE.—*Glass not less than ¼in. thick in sections not exceeding 36in. super., and wired glass not exceeding 1in. mesh, in sections not exceeding 144in. super., in either case set in metal, shall for the purpose of this rule be deemed incombustible.*

Outlets on to roofs rendered necessary to satisfy the requirements of the Factories and Workshops Acts permitted, provided that all doors and frames be of iron or cased in iron plate at least ⅛in. thick, and that they be self-closing.

Protection of Structural Metal Work.

14. All columns or stanchions to be covered with brickwork or porous terra-cotta (at least 2in. thick), or with cement, concrete, or plaster at least 1½in. thick, keyed into metal supports and protected by a metal guard up to a height of not less than 4ft. from the floor where cement, concrete or plaster only used.

15. Girders, joists, lintels, and all structural metal work (other than columns and stanchions, but including framework of roofs), where not covered with brickwork, to be completely encased in porous terra-cotta at least 2in. thick, securely anchored, or cement, concrete or plaster at least 1in. thick keyed in metal supports.

16. Space must be left at the ends of girders and joists to permit of expansion.

Linings and Ceilings.

17. No lining of wood or textile fabrics to any part of the walls, partitions, ceilings, or roof.

Floor Openings.

18. No openings through any floors allowed except as follows:—

(*a*) Holes to admit driving shafts, pipes, and iron or earthenware tubes for electric conductors. Shafts to fit closely in metal collars, and all pipes and tubes to be cemented round the full thickness of the floor.

(*b*) Staircases and hoists of which the enclosures are constructed entirely of brick or cement-concrete as above described at least 9in. thick, with a regulation 'fireproof" door to every opening.

N.B.[1]*—Stairs and landings within said enclosures to be constructed of incombustible material.*

N.B.[2]*—Where the building is within the City of London or in the area controlled by the London County Council, hardwood doors to openings may be allowed instead of "fireproof" doors.*

N.B.[3]*—Where the staircases and hoists extend to the top floors, they must have a glass roof protected externally with strong wire-work, and the enclosing walls must be carried through and 18in. above the roof of the building.*

In factories and workshops in the area controlled by the London County Council a glass roof protected as above is only to be provided in cases where the enclosing walls and staircases are carried through and 18in. above the roof of the building, and also above the roof of the adjoining premises. Otherwise the roof must comply with the requirements of the London County Council.

(*c*) Belting and rope races enclosed as for staircases and hoists.

Shafting through Walls.

19. Shafting where passing through walls to fit closely into wall, or have wall-boxes closed with iron plates not less that ¼in. thick, leaving no open space.

Pipes and Electric Conductors.

20. All pipes in the building, except water-pipes not exceeding 1½in. in diameter, to be of hard metal. No wooden casing to be used for enclosing electric conductors.

Communicating Compartments.

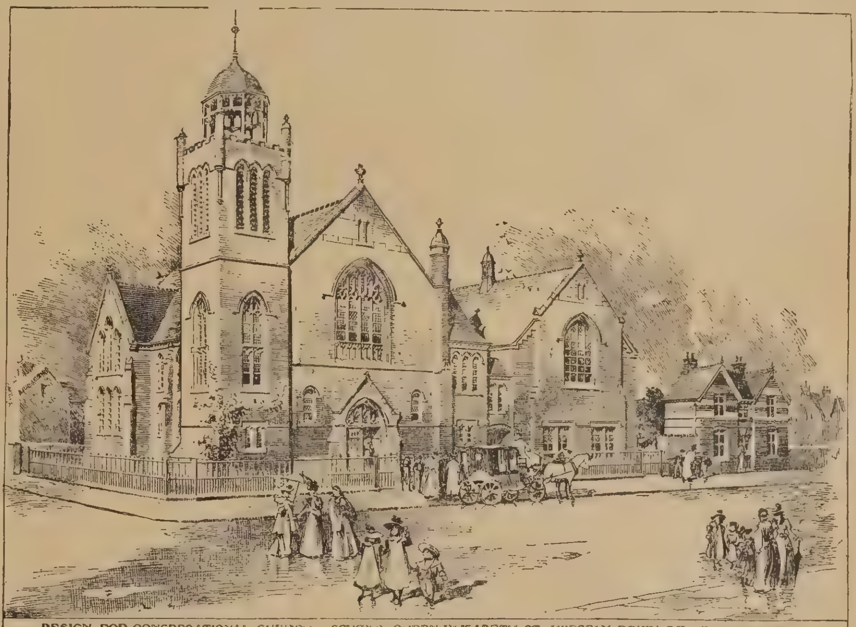
21. Two or more compartments, each constructed in accordance with these Rules, may communicate whether by double "fireproof" doors or otherwise, provided that their aggregate cubical contents do not exceed 60,000 cub. ft.

22. Two or more such compartments, whose aggregate cubical contents exceed 60,000 cub. ft., can only be allowed to communicate across a "fireproof" compartment, built up from the basement with walls of solid brickwork, and constructed in all other respects in accordance with these Rules so far as the same are applicable, and having all openings protected by "fireproof" doors at least 6ft. apart.

23. Except as above, no communication allowed between a compartment constructed in accordance with these Rules and any other building or compartment.

A SOUTHWARK CONGREGATIONAL CHAPEL.

A NEW Union Congregational Church and Schools, now in course of erection on the southern side of the Tower Bridge, will take the place of the old buildings in Parish Street, Horselydown, S.E., acquired by the South-Eastern and Chatham Railway Company in connection with the widening of their lines. The new buildings consist of two blocks, one comprising the church, with ground floor and galleries, and an orchestra behind the rostrum; also minister's vestry, choir vestry, deacon's vestry, lavatories, &c., and organ-chamber. This block is placed at the junction of Queen Elizabeth Street and Horselydown Lane, and has a tower at the corner 12ft. sq., terminating with four corner octagon pinnacles with ogee terminals, and an oak cupola, with ogee top, covered with lead, and wrought-iron terminal, the whole rising to a height of about 70ft. The walls are of brick with stone dressings, and the interior of the church will be fitted up with pitch-pine. The roof will be partially open, the timbers being arched and the ceiling of pitch-pine. The rostrum will also be of pitch-pine. The school block will consist of assembly-room and five classrooms. The church will accommodate 490 adults, or a mixed congregation of 625 persons, and the school block 400 children. Both blocks are connected at front and rear by lobbies and staircases. There is also included in the scheme a caretaker's lodge. The cost of the work is about £6,700, but with cost of site, &c, the gross total will be £10,950. The architect is Mr. John Wills, F.S.Sc., of Derby and London, and the contractors Messrs. Battley, Sons & Holness, of Old Kent Road, S.E. The illustration on this page has been kindly lent us by Mr. George Reeve, the secretary to the trustees and deacons of the church.



DESIGN FOR CONGREGATIONAL CHURCH & SCHOOLS QUEEN ELIZABETH ST HORSELY DOWN SE

JOHN WILLS F.S.Sc. ARCHITECT DERBY & LONDON

Builders' Notes.

Mr. James J. Bickerton, painter and decorator, of Alnwick, died recently.

Mr. T. Huntington, builder and contractor, of Mexborough, died last week.

Mr. Stephen England, builder and contractor, of St. Annes, died recently at the age of sixty-seven years.

Mr. Peter Cunningham, of Dunbar, died recently. He was a partner of the late firm of P. & G. Cunningham, builders.

Mr. E. Pinnell, builder and contractor, of Wotton-under-Edge, died recently at the age of ninety-two years. He retired from business about sixteen years ago.

Mr. John Noy Trounson, manager of the Penzance Gas Works, and an architect and builder, died last week at the age of eighty-four years.

Builders' Bankruptcies.—In the Bankruptcy Court last week the public examination of W. H. Gibbs, builder, surveyor and estate agent, of West Kensington and Fulham, was held. Debtor returned his gross liabilities at £245,113 (of which £21,651 are unsecured) and assets showing a surplus of £48,246. The examination was adjourned.—In the same Court W. G. Hornsey, a builder, of West Ham, applied to pass on accounts showing gross liabilities £128,022 (of which £10,515 are unsecured) and assets showing a surplus of £55,027. The examination was adjourned.—A meeting of the creditors of C. L. Schofield, builder, of Oldham, was held last week in the Official Receiver's office. The statement of affairs showed gross liabilities £25,200, amount expected to rank as dividend £1,842, and assets estimated to produce £2,332.

The Builders' Foremen's Association held its eighth annual dinner at the Holborn Restaurant on Saturday evening last. There were over 200 persons present, and the chair was occupied by Mr. G. Cakebread. In replying to a toast, the president, Mr. H. J. Strong, said the Association was formed nine years ago in a small way, but now numbered over ninety members. Its objects were to promote the interests of those engaged in the control and supervision of building and kindred works by providing a central place where meetings and discussions could take place from time to time on matters of interest to the building and allied trades. There was a benevolent fund for members in need, and £10 was paid on the death of a member. Since its foundation over £100 had been paid in benevolent grants, and the invested funds were now over £160. The monthly subscription was 2s. 3d. A musical programme was rendered during the evening. The secretary of the Association is Mr. W. Cook, 42, Amwell Street, E.C., who will furnish all particulars.

Keystones.

The Queen Victoria Memorial Fund now amounts to about £187,000.

The Sir John Cass Technical Institute, Aldgate, was opened last week.

A Bust of Sir Frederick Bramwell, by the late Mr. Onslow Ford, has been placed in the Royal Institution, Albemarle Street, W.

Mile End Public Library.—The Stepney Borough Council have had the hall of the vestry of Mile End Old Town in Bancroft Road opened as a free public library. The whole of the hall on the first floor is arranged as a reading-room.

Dalham Hall, near Newmarket, has been purchased by Mr. Cecil Rhodes. The hall is an imposing structure in the Georgian style, and was erected in 1704. Messrs. Maple have now a staff of workmen engaged in fitting up a suite of rooms at the mansion. The extent of the Dalham estate is about 3,500 acres.

R.I.B.A. Colonial Examination.—The Royal Institute of British Architects have decided to hold an examination in Melbourne from July 4th to 10th next to qualify for candidature as Associate of the Institute. They have appointed Mr. G. C. Inskip, F.R.I.B.A., and Mr. Ponkden, A.R.I.B.A., of Melbourne, as the Examining Committee.

Belfast Building By-laws.—The Ulster Society of Architects has made objection to the Belfast Corporation against the proposed building clause of the new Bill referred to on p. 343 of our issue for January 1st, but the Corporation have refused to alter the clause. Sir Samuel Black explained that the clause as it stands is intended to secure uniformity in the height of buildings.

A "**King Edward VII. Home for Nurses**" is to be erected adjoining the main building of the North Staffordshire Infirmary at Stoke-on-Trent. The building is to accommodate fifty nurses, and is to be joined to the Infirmary by a covered way. It is intended as a memorial of the Coronation year of the King, who, with his Consort, as Prince and Princess of Wales, laid the foundation-stone of the main building of the Infirmary in 1866. The cost is estimated at £10,000.

The Local Government Annual, 1902.—Several additions have been made to the eleventh issue of this book, which is indispensable to all engaged in local government affairs. The names of committee chairmen in the Metropolitan boroughs, and the chairmen and vice-chairmen of the London County Council committees, are given for the first time. There is also much new and useful information relating to the public libraries, baths and washhouses, and electric light undertakings in the boroughs of London, and the abstract of the Local Government legislation of 1901 cannot fail to be of service. The book is published at 2, Dorset Street, Fleet Street, E.C., price 1s. 6d.

Excavations in Greece.—At the Royal Institution last Thursday Dr. A. S. Murray, of the British Museum, began a series of three lectures on "Recent Excavations at Delphi and in the Greek Islands." His first lecture dealt with the French excavations at Delphi, which had now been laid almost bare, the plan showing a sacred way winding up to a temple at the summit. Along this way were a number of small buildings, called "treasuries." Of the Temple of Apollo little besides the stylobate remained, which however allowed the plan to be traced. The fragments found hardly allowed the "Order" to be formed. The most important remains found were of the Treasury of Cnidos, a small building less than 30ft. square, which had a finely-sculptured frieze. In place of columns two caryatid figures were used on the front; but although these were far from being so refined as the later sculptures of the Erectheum at Athens, they were their prototypes. Archaic sculptures from the Treasuries of Athens and Sicyon, on the sacred way, were also shown, and Dr. Murray drew the conclusion that the art of sculpture was in the sixth century B.C. trammelled by conventionalism, but the sculptors, as the poets, of that date were possessed of originality, which made it possible for the sculptors of a later date, by revising and improving, to produce their masterpieces.

At Victoria Hospital, Burnley, an operating theatre has been built at a cost of over £1,000.

New National Schools at Winslow, Bucks, have been opened at a cost of £2,700.

Mr. Joseph Toone, architect, of Leicester, died last week at the age of fifty-seven years.

The City boundary on the Embankment is to be marked by the erection of a bust of Queen Victoria, sculptured in relief, on a pediment, like that on which the Griffin at Temple Bar now stands.

Eton College Chapel is to be restored by Messrs. Wheeler, of Reading, who will repair the stone mullions and effect re-leading where necessary of the great stained-glass window on the north side of the choir.

A new Post-Office for Pudsey is to be built by Mr. E. Walker, of Armley, the owner of the site, in the centre of the town on the Waver Green Estate, adjoining the Market Place and the Municipal Offices, the Post-Office authorities taking it on a long lease.

Belfast Mill Floor Collapse.—At the moment of going to press we learn of the collapse of the fourth floor in the mill premises of the Smithfield Flax Spinning and Weaving Co., Belfast. This, it is stated, gave way without the slightest warning, a large quantity of machines cutting through the lower floors to the very bottom and burying the workers. It seems that this terrible catastrophe was caused by overloading, to the dangers of which we drew attention only last week.

Mansfield Parish Church, in order to provide for the largely increased congregations, is to be enlarged from plans by Mr. C. Hodgson Fowler, F.S.A. It is estimated that the provision of an organ-chamber, with the requisite attention to the chapel now largely occupied by the instrument, will cost between £600 and £700. The chamber will be erected on lines which will enable it to form an integral part of a more ambitious scheme, should the further extension of the church be decided upon at some future date. Both side chapels will thus be utilised by members of the congregation.

A Congress of the Sanitary Institute will be held at Manchester on September 9th-13th, 1902. The Right Hon. the Earl Egerton of Tatton will be the president. Section I.—Sanitary Science and Preventive Medicine—will be presided over by Sir J. Crichton Browne, M.D., LL.D., F.R.S., F.R.S.E. Section II.—Engineering and Architecture—will be presided over by Sir Alexander Binnie, M.Inst.C.E. Section III.—Physics, Chemistry and Biology—will be presided over by Prof. A. Sheridan Delépine, M.B., C.M., B.Sc. Eight technical conferences will also be held in connection with the Congress.

A New Street at Perth is being formed between South Street and High Street. The first block or feu has been taken for premises to be erected for Messrs. Stewart & Dick, wholesale provision merchants and commission agents. The elevations are to be of red stone. Mr. David Smart, of Perth, High Street, is the architect. The contractors for the work are:—Mason, Robert Brand & Son; joiner, Hay & Sim; slater, James Buchan & Son; plumber, James MacLeish (all of Perth); and plasterer, Alexander M'Ritchie, Dundee; while the steel beams are to be provided by P. & W. MacLennan & Co., of Glasgow.

Architects and Commercialism.—In the course of a lecture delivered last Wednesday at the Manchester City Art Gallery, Mr. J. E. Phythian, president of the Manchester Ruskin Society, referred to the lecture recently delivered at Owens College by Mr. Reginald Blomfield on "Municipalities and Architecture" (reported in our issue for December 18th last). Mr. Phythian said that Mr. Blomfield had blamed commercialism for the lack of appreciation of architecture by the average man, and for the hideousness that surrounded us; but he (the speaker) asked whether artists were not themselves to blame for commercialism to some extent? Mr. Blomfield had tried to prove that Ruskin was an untrustworthy guide with respect to architecture, but his method of proof was mere depreciation and inaccurate statement. It was certain that the Gothic revival was brought about not in obedience to a purely literary sentiment, but from a distinct love of the forms of Gothic architecture.

THERE ARE STILL

a few of our readers who have not availed themselves of the advantages of

Our Insurance Schemes,

which include

(1) *A Free Accident Insurance of* **£500** *to every regular reader of our paper.*

(2) *An Accident Insurance of* **£500,** *and also*
£250 *for Permanent Total Disablement.*
£2 10s. *per week for Temporary Total Disablement.*

Premium, 1/-

(For the conditions under which policies Nos. 1 *and* 2 *are issued readers should refer to our pamphlet, sent on application.)*

(3) *An Accident Insurance of* **£1,000,** *with the following special additional advantages:*
£500 *for Permanent Total Disablement.*
£6 *per week for Temporary Total Disablement.*
£1 10s. *per week for Temporary Partial Disablement.*
£30 *Annuity.*
£3 *per week during confinement from such illnesses as Small Pox, Diabetes, Scarlet Fever, Carbuncle, &c., &c.*

Ordinary Risks, Premium, £3/-
Hazardous Risks, Premium, £3/10/-

Write for Proposal Form.

These Insurances are guaranteed by the Ocean Accident and Guarantee Corporation, Limited.

SPECIAL NOTICE.

(1.) It is not necessary to subscribe direct to the office in order to secure the benefits of the above schemes.

(2.) Even if ordered through a newsagent the subscription need not be prepaid for a year. It is sufficient to order it and pay as may be arranged with the newsagent.

(3.) It is sufficient for us to have an intimation from the newsagent that he supplies copies regularly.

(4.) Policies can be issued either direct to the subscriber or through the newsagent, whichever may be preferred.

(5.) In applying it is only necessary to write a postcard, giving the full name and address of the newsagent from whom the copy is obtained.

A Pamphlet, giving full details of the THREE SCHEMES will be sent on application to

THE MANAGER, BUILDERS' JOURNAL
EFFINGHAM HOUSE, ARUNDEL ST.,
STRAND, W.C.

COMPLETE LIST OF CONTRACTS OPEN.

DATE OF DELIVERY		WORK TO BE EXECUTED.	FOR WHOM.	FROM WHOM FORMS OF TENDERS MAY BE OBTAINED.
		BUILDING:		
Jan.	23	Bolton, Lancs—Retort and Fireclay Goods	Gas and Lighting Committee	W. Walch, Office Superintendent, Gas Offices, Bolton.

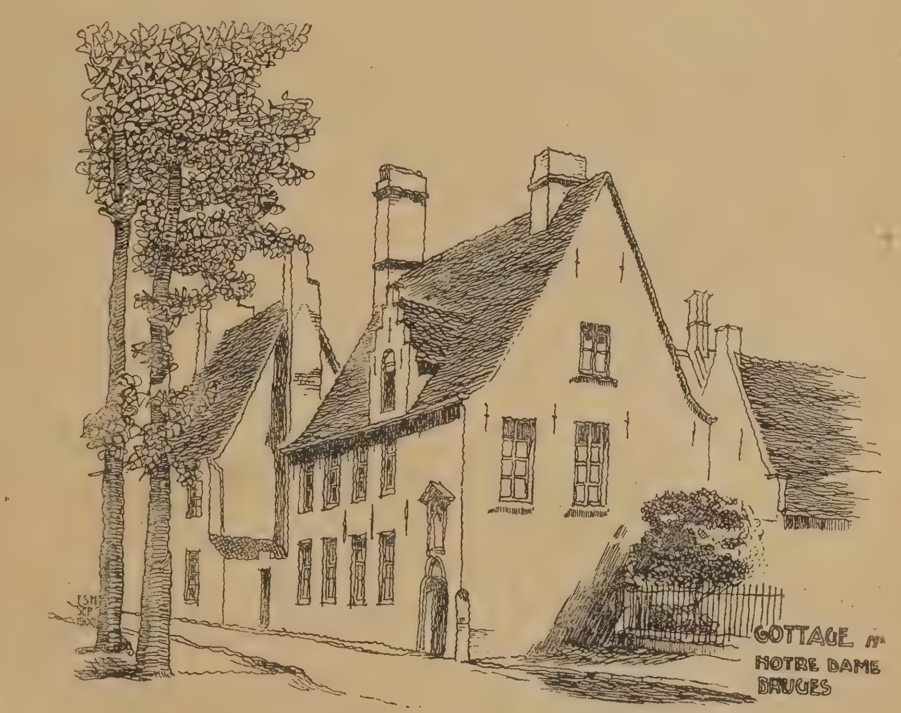
An Architectural Causerie.

Unsafe Buildings. THE cause of the Belfast disaster, which we were able to briefly report in our last issue, has not yet been ascertained, though several conjectures have been made. The managing director of the firm, Mr. Arthur Herdman, repudiates the suggestion that the older portions of the building were unsound, as when extensions were being made to the premises about eight years ago the addition of another storey was contemplated, and after a careful examination it was found that the walls were quite capable of supporting this extra weight. However, as the firm found they would obtain more room by building a new department, the additional storey was not erected. It has been suggested that the regular vibration of the numerous machines employed in the factory set up an accumulated effect which ultimately resulted in this disaster, but such an inference is not logical, as the spinning machines used would not, by their very nature, have the effect suggested. This reflection of the effect of vibrating machinery on building structures is, however, interesting, though it cannot be classed among such examples as that of the boy who, by constantly and regularly projecting a pea on to the arch of Waterloo Bridge, could ultimately wreck it; or the instance of a body of men who are required to "break step" when marching over a suspension bridge. The cause of the Belfast disaster will probably not be ascertained until the Board of Trade enquiry is held, but everything seems to point to our original assumption—overloading on the upper floors. Whilst referring to this subject it is opportune to note that the Improvement Committee of the Manchester Corporation has decided to appoint Mr. William Wilson, an official in the city surveyor's department, as inspector of dangerous buildings, the salary being £230 per annum. The object is to prevent accidents similar to the one which occurred on the occasion of Lord Roberts's visit to the city, when a woman was killed by the fall of a coping-stone in Deansgate; a fatality which we commented on in our issue for October 23rd last.

Shams. THE present is an age of many things, and amongst others it is an age of shams. So insidious has been their production and so demoralizing their effect, that people regard them with tranquillity and even with admiration; and the misfortune is that the practice of making imitations is increasing in all branches of industry. Taste doubtless changes with the times, but if a thing has some logical reason for its being and construction it will outlive the fashion of the moment, though it be the fashion itself. Take doors as an instance. Suppose a front door is wanted for a suburban house, and that deal instead of oak has to be used on account of expense. To leave it unprotected is obviously a mistake, as the rain will drive into its pores, swelling the joints and rotting the wood. Consequently it is painted. This is perfectly justifiable; and if the door has been well designed and made, however plain it be, it should be as satisfactory to one generation as to the next But why spoil everything by graining? Why spend money on trying to make it look what it isn't? The idea is absurd on the face of it, yet the reason for this "embellishment" is that the general taste is so demoralized that people have come to regard plain things as necessarily ugly, and hence to be avoided; whereas they are courting ugliness in its worst form—fraud. This subject of graining is perhaps a hackneyed one, but some good has certainly resulted from the tirade against the practice, and we see more houses with neatly-painted windows and doors than formerly. The passion for graining has invaded the inside also, and besides sham skirtings, dados and picture rails there are even cast-iron chimney-pieces grained to look like walnut! When one arrives at articles of real wood another difficulty presents itself, one which is also due to the popular hatred of anything plain. Let any person with taste look upon those walnut overmantels and sideboards which are the joy of the furniture dealer. Has one anything but contempt for the puerile "carving" or the turned knobs and pillars which so commonly get loose because they have never been properly fixed, or for that bugbear, the pediment with rosettes? And, to add to the effect, there must be generous application of varnish and polish. Yet this is the kind of stuff which people of standing fill their homes with. Then, again, consider how sham half-timbering is regarded by the public—the intelligent public. They say it looks the same as the genuine construction, and the house holds up; so what, they ask, can be the objection to it? These people would regard as clever the painting of dummy windows (with the blinds down) on a blank wall space, or they might even go so far as to approve the erection of imitation ruins. Similarly, they will use celluloid articles which imitate ivory and tortoise-shell, stained wood for ebony, imitation old furniture, imitation inlay work, sham stained glass, gas fires with logs of wood in them made of fireclay, and the hundred-and-one other shams of to-day. It is true that in some cases these things are forced on them—such as marbled slate mantelpieces which are in their house when they rent it—but they need to be roused from their state of complacency and to appreciate the fact that when an article is what it pretends to be, that is something in its favour; and that when it pretends to be something which it is not, then it should be avoided on every possible occasion. By constantly dinning this into people's ears one may hope for some improvement taking place; and both the individual and the community will benefit by it.



COTTAGE AT NOTRE DAME BRUGES

DRAWN BY F. STANLEY MITTON.

Glazed Tiles. MR. HALSEY RICARDO'S paper on "The Architect's Use of Enamelled Tiles" is not only useful and interesting for the excellent critical history it furnishes of this subject, but also for the many conclusive arguments which the author puts forward for a much more extended use of glazed tiles on modern city buildings. His two remarks that "for half the year our city is the colour of a dirty cobweb" and "the ordinary brick wall is nearly as thirsty as a sponge-cake" summarize very well his plea for more colour and illustrate the fact in its favour that a thin glazed skin will more effectively keep out damp than a thick porous one; so the weight of walls could be reduced. While we agree that a glazed street architecture is suitable to dirty cities, we fear there is little hope at present of seeing it carried out on the large scale which Mr. Ricardo considers essential to success. The Birkbeck Bank is a glazed building, but the flagrant abuse of the material utterly condemns it. "The colour must be laid on in a broad bold mass, and pattern used only sparingly"—not allowed to go rampant, as on this bank.

A Cottage at Bruges. BRUGES, which in Flemish means "bridges," a name due to the many picturesque bridges crossing the canals, was the great commercial centre of Europe in the fourteenth century. Of its architectural beauties the belfry is the chief, towering up 352ft. It was begun in 1282 and finished at the end of the fourteenth century. Notre Dame is a church surmounted by a tall brick tower, a fine work dating back to 1230, with a modern spire which rises to 442ft.; the nave and inner aisles belong to the year 1180, while the outer aisles date from 1480 to 1520. The pulpit is of wood, elaborately carved, a feature common to churches in the Netherlands. Close to Notre Dame is the delightful cottage shown in the accompanying sketch.

SICILY AND ITS ARCHITECTURAL MONUMENTS.—II.

By F. HAMILTON JACKSON, R.B.A.

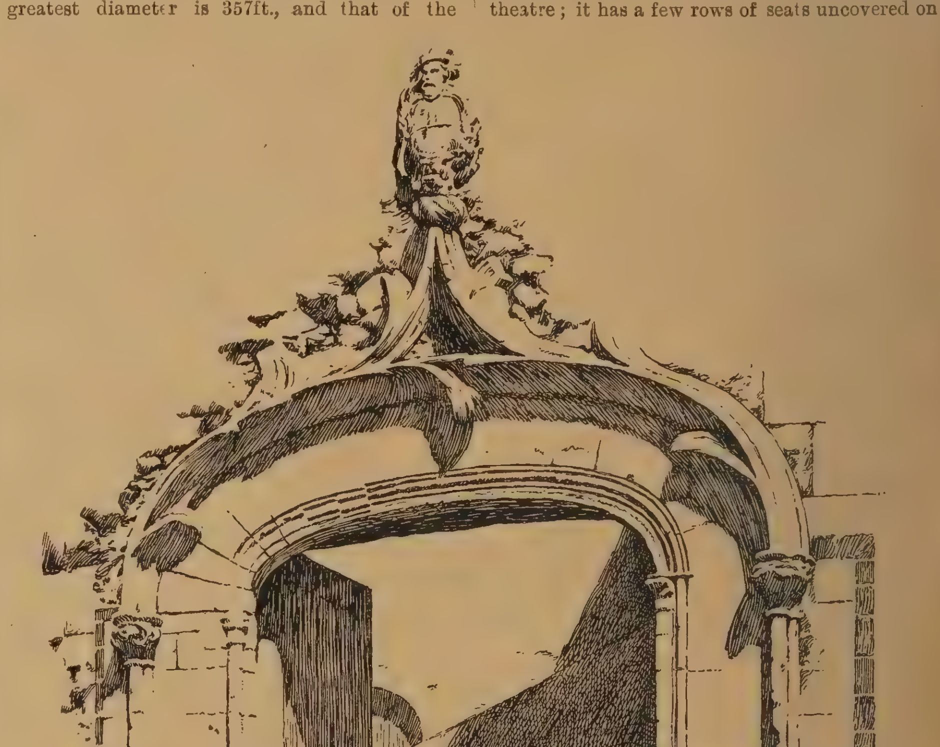
(Continued from p. 377, No. 362.)

TAORMINA lies on the side of a hill, called Monte Tauro, above the station of Giardini, and about three miles from it by the new road, though it may be reached in half an hour by means of a steep mule-track. As it is nearly 400ft. above the sea, extensive views are commanded by many points, both inside the town and immediately beyond the gates, looking in both directions. To the south Etna dominates the landscape, the sweeping curves of the coast leading the eye towards it, and the lines of the hills as they decline towards the sea contrasting and emphasizing its enormous bulk. From this side the height of the mountain is not so striking, the slope of the sides being exceedingly gradual, owing to the large space covered by the outlying spurs, and indeed it is difficult to realize that its summit rises to the height of 10,742ft. To the north the view is bounded by the mountains above Messina, while the mainland shows pale and delicate across the strait, and the coast-line is broken by the beautiful capes of S. Andrea and Taormina. The line in both directions runs by the coast, a practice which much conduces to the pleasure of the traveller, and which most of the Sicilian railways follow; and the journey, especially if made by a slow train (which is never crowded, so far at least as the second- and first-class carriages go), is most interesting and the scenery delightful. Many "fiumare" are passed, broad expanses of stone with occasionally a pool or two of water still remaining, but used by the country people as roads during a great part of the year, as is evidenced by the beaten track which meanders along by the side walls which confine the flood when it comes—as one must suppose it sometimes does, or why the elaborate and extensive preparations? At such times one is inclined to wonder how the people get about, forgetting that these river-roads are only auxiliary to the main highway. Many of the hills, at least the lower spurs, are crowned with castles or monasteries, most of them in ruins, but a few still inhabited. Those of the former category form the greater addition to the picturesqueness of the landscape.

The town is asserted to be of Siculan origin, or even Sicanian; at all events, after Naxos was destroyed by Dionysius of Syracuse, in 403 B.C., the Siculi who were established there went up to Monte Tauro and disappeared among the inhabitants of the city which was already there, and of which they appear to have erected or rebuilt the acropolis in gratitude to the gods for their release from slavery. (This was on the height above the town, where the ruins of the Saracenic castle may still be seen.) Andromachus (396–352 B.C.) was the name of the ruler who received them, the father of Timæus the historian, whose hatred of tyranny and love of liberty were probably the result of the example and teaching of his father, whose character was a great contrast to that of the usual tyrant. He it was who invited Timoleon and his Corinthians into Sicily, and it was from his house that the latter set forth on the triumphal march which freed Sicily for a time from tyrants and Carthaginians. The ancient name was Tauromenium, a name which it bore for a long time and of which the modern name is a corruption; but after the third taking of the town by the Mussulmans it was named Muezsiya by Hassan-el-Muez, its conqueror, who also introduced a colony of Mussulmans. The second taking was by the bloodthirsty Ibrahim-ibn-Ahmed, in 902—at the same time that Mola, the inaccessible-looking village on the hill beyond the castle, was taken and the whole population massacred. They only held undisputed possession of the town for 100 years, since the Normans took it in 1078, a capture which was most advantageous to the place. At one time the population, which is now but 3,000, must have reached 100,000, if the size of the theatre may be taken as any criterion. It was one of the first cities to protest against the tyranny of Verres, throwing down the statue which the pro-consul had erected in the forum, and here a number of slaves established themselves during the first Servile war, offering a long and obstinate resistance to the soldiers. Together with Mola, it has been the scene of many romantic deeds of arms; and when one considers their apparently impregnable position, situated far up steep rocks, one wonders how it was possible to take either before the invention of gunpowder.

The most important building in Taormina, and the one which is the principal object of attention, is the theatre, erected in Greek times, but reconstructed by the Romans, under whom the town was very flourishing. The local authorities have the liberality to leave it open from 7 in the morning to 6 in the evening, so that one is able to go again and again and see it under different conditions of light and shade, and even, if one pleases, follow the guide-book directions and see the sunrise from that point of vantage; for the custodian, who lives in a little house on the summit of the rock, is very civil, and makes no difficulty about leaving the gate unlocked if requested.

The proscenium is well preserved, as such things go, and, indeed, there are but two others—those of Aspendus, in Pamphylia, and that of Orange—which are in so complete a state. Its greatest diameter is 357ft., and that of the orchestra is 126ft. The back wall is two storeys in height, and has had some of its original decorative details re-erected. Three entrances are provided, and between the centre doorway and each of the two outer ones are three niches, and on the further side of each outer doorway one niche for statues. The stage is narrow, on the Greek plan, and beneath it is a vaulted channel in which the rainwater from the rest of the theatre was collected and through which it passed away. The seats were divided into nine "cunei," or sections; around the top ran a corridor, the upper "præcinctio," which belongs to the Roman period, since the wall (which is coved on the exterior at the top) crosses diagonally the remains of a Greek house or temple. Steps remain, and some rough mosaic floors within the walls, made of irregular pieces of white marble on a ground of broken pottery, looking much like "opus signinum." According to an inscription behind the stage, the theatre was destroyed by the Saracens, but the greatest destroyer was the Duca di San Stefano, who employed its marble ornaments in the decoration of his palace. Behind S. Caterina, close to the Palazzo Corvaia, are the remains of a small Roman theatre; it has a few rows of seats uncovered on



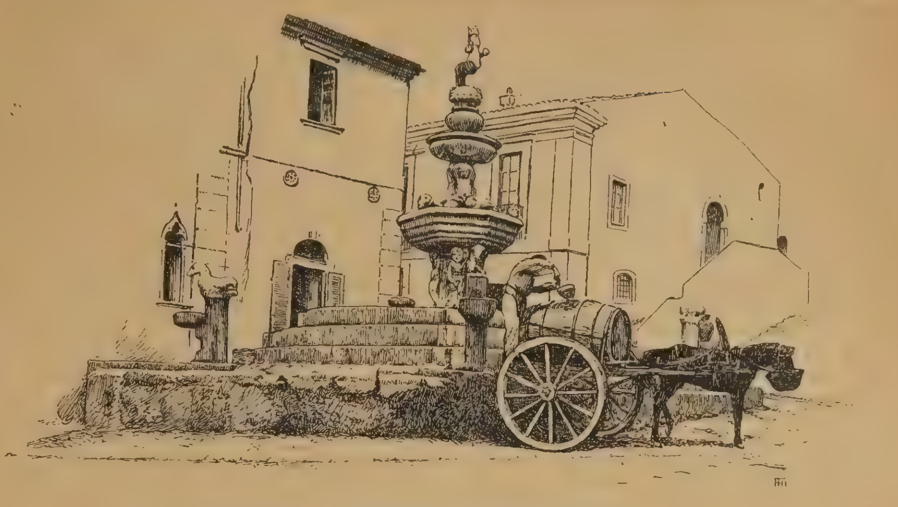
DOORWAY, PALAZZO CORVAIA, TAORMINA.

one side, and a vomitorium in the middle, the vault of which is oval in section. The church of S. Pancrazio, outside the Messina gate, is the cella of a Greek temple, and, with a Roman bathing establishment called the Naumachia, without any authority for the name, exhausts the antique remains of the city.

The mediæval buildings are almost as interesting. The first place must be given to the Palazzo Corvaia, a building perhaps of thirteenth-century origin, but which appears to be of the fourteenth. It has two-light windows with ogee hood moulds, and inlays of lava in string-course and cornice, while the wall is furnished above with forked battlements. In the courtyard is a fourteenth-century relief representing the creation of Eve, the Fall, and Adam delving while Eve spins. An outside staircase ascends to the *piano nobile*, in the great rooms of which are traces of wall frescos. Here it was that in a large hall (now given-up to chickens except where used for the purpose of storing corn and beans) a general parliament was held, promoted by Bernardo da Caprera, Count of Modica, which on the death of Martin the Second without direct heirs, in 1410, gave to Sicily a national king in the person of Caprera himself, already grand justiciar. It was but two years later that the jealousies of the barons called in the Castilians.

The north door of the cathedral is of the fourteenth century apparently, but the interior is rather earlier. The nave arcade consists of large columns with roughly-cut caps. On the left, near the high altar, is a seat raised on four steps, the whole of red marble, probably for the seigneur, or the signory; opposite are the seats for the celebrant and his assistants, made of wrought iron, a very unusual feature. On festa days the first mass is said at the unearthly hour of 3.15 a.m. A fountain in the piazza is picturesque, but not ancient, though some of the sculpture is very much worn. The Palazzo S. Stefano, called also S. Germano, is said to be the palace for the construction of which the theatre was stripped of its marble. It is a late thirteenth-century building, though portions of it look earlier. The windows and the curious crowning feature inlaid with lava are similar to another facade higher up the hill, now unfortunately a mere shell, La Badia Vecchia, which has three pointed windows of two lights each with tracery above and a more lavish use of inlay. In the crypt of the Palazzo S. Stefano is a central column of Greek marble, which supports the vault, the capital of which is also of marble but with late thirteenth- or early fourteenth-century carving. This room was used as a bath, though only accessible from outside, and in the wall the conduit through which the water flowed still remains, leading to a curious pit-like sinking, about 4ft. deep, in a triangular space sunk about 1ft. below the floor-level. The whole is lined with marble. The water at that time came from Monte Venere, but the modern supply comes from a less distance. Another palace, the Palazzo Giampoli, stands at the top of an imposing flight of steps. It has a Renaissance doorway and window of graceful proportions at the side, though itself thirteenth or fourteenth century. Others of the ancient palaces have either pointed windows of several lights, or doorways of the type of that illustrated.

A few balconies with Spanish-looking ironwork are to be seen, but for the most part Sicily is rather bare of this kind of interest, and Taormina is not exceptional in this respect. The names of the streets were scrawled up in red paint, but neat tablets of roughened grey marble, with the letters and border polished, are superseding without destroying them. At the end of the town, beyond the Porta San Pancrazio, is a curtain wall leading to an outlook post. From this place a fine view of the town may be had, and one looks right down upon the monastery of S. Domenico (now an hotel), the sacristy of which contains some fine Renaissance carving in frieze, pilaster and panel; there are also carved stalls in the monks' choir, behind the high altar, of similar style, and in a chapel at the bottom of the church is an interesting early monument. Of the Saracenic period the remains are the castle on the hill and portions of the walls, for there is more than one line of defence, but to the untrained eye the difference is scarcely perceptible. A few wall fountains make picturesque bits of light and shade; and from the main street delightful glimpses of sea and distant country appear down precipitous alleys, while from the two or three piazzas more extended views may be had; for it may be repeated that the greatest charm of Taormina is the beautiful view over mountain and sea which is visible from so many points in and about the town, and the lovely sunsets and sunrises, which the early habits of the place (they milk goats at your door at 6 a.m.) stimulate the traveller into seeing many more of than he would at home.



FOUNTAIN IN CATHEDRAL PIAZZA, TAORMINA.

The main line from Taormina to Catania continues to run by the sea, with the slopes of Etna on the right hand, from which numerous lava streams have descended at different dates. On the northernmost of these stands the Castello di Schisò, which indicates the site of the ancient city of Naxos. A little further on is another ancient lava stream, where the road to Catania viâ Randazzo diverges—one which in B.C. 396 prevented the Carthaginian general Himilco from proceeding direct to Syracuse after the destruction of Messana, and compelled him to march round the mountain. Timoleon also followed this route in 344 B.C., and Charles the Fifth in 1534. Above Giarre, a station which serves two villages between which it stands, in the common Sicilian fashion, are the remains of the gigantic chestnut tree called "di Cento Cavalli" (of the hundred horses), that being the number which its spreading branches were reputed to have sheltered at one time, and several other famous old trees. This is the place from which the Valle del Bove and the craters which were active in 1865 are best reached. It is thought that the original crater of the volcano is above this "Valle." Several more lava beds are crossed, and Acireale is reached, standing among its orange groves and olive woods, a prosperous and quite uninteresting place with warm mineral springs, rebuilt after the earthquake of 1693, but the locality of the myth of Acis and Galatea; while a little further on the rocks of the Cyclops hurled by Polyphemus at the escaping Ulysses may be seen at Aci Castello, where the picturesque old castle combines with them and the coast-line to make a delightful picture. More lava streams are crossed and the line descends towards Catania, which it enters on its least attractive side.

(To be continued.)

A Record of the Repairs to Winchester Cathedral has been cut in stone and recently placed in the west end of the nave. It states that the repairs to the roof were begun in March, 1896, and finished in December, 1898; the cost was £12,670 10s. 11d.; and the total area treated, 31,973 ft. super., or about three-quarters of an acre; weight of lead removed and recast, 156½ tons, put on 197½ tons; weight of new oak, 198¼ tons; weight of pitch-pine in battens, &c., 326¾ tons; length of battens, 93,510ft., or about 17 miles. The work was carried out by Mr. J Thompson, of Peterborough, under the supervision of Mr. J. B. Colson, F.R.I.B.A. A good deal of necessary work on other parts of the roof remains to be done.

THE ARCHITECT'S USE OF ENAMELLED TILES.*

BY HALSEY RICARDO.

THE architect's use of enamelled tiles may be classed, for convenience sake, into three divisions, according to the purposes for which he uses them—either on hygienic grounds; for the purpose of saving or reflecting light; or for decoration. These three divisions blend, of course, into each other, and sometimes all three objects are obtained simultaneously in one scheme of tile-work. Thus, the staircase hall in Lord Leighton's house presents a wall whose surface can be thoroughly and easily cleaned; whose glaze checks the diffusion of air, dirt and moisture; which retains its light and colour even in the darkest corners; and which by its pattern and hues constitutes a beautiful scheme of decoration.

More often a combination of two requisitions only is secured, as in the case where tiles are used to line underground passages, railways, lavatories, dark rooms and courtyards. In a dairy, to take another example, the decorative as well as the hygienic aspects of the case are sometimes considered. But for the present I shall pass by the builders' and plumbers' use of the material, and shall consider mainly the employment of

Enamelled tiles as a Mode of Decoration.

Incidentally for this form of decoration I shall claim the collateral advantages it affords both as regards the economy of light and the wholesomeness of the practice of covering one's walls with an impervious glaze; but the decorative treatment is what I shall most concern myself with, considering its use and the limits of its use, and what should be the architect's attitude in regard to this method of architectural enrichment.

In referring to the examples of tile-work in the past, I shall allow myself some latitude in my definition of an enamelled tile, for I shall want to cite the Assyrians' use of glazed bricks, the Persians' treatment of glazed terra-cotta and the Della Robbias' of glazed earthenware; the differences, however, which are so apparent are not essential, but arise from the nature of the material.

A glazed brick is only a thicker tile and a glazed plaque but a wider one. An enamelled tile, then, is a slice of terra-cotta with its face glazed with white or colouring matter put on it or in the glaze. As a rule, the terra-cotta foundation has a distinct colour of its own, which shows through and modifies the effect of a transparent stained glass poured over it. To obviate this—when the simple result is undesired—there are

Two Methods

generally practised; one, to render the glaze partially or entirely opaque, by the admixture of oxide of tin; the other, to mask the surface of the terra-cotta with a film of white ware or porcelain (technically known as slip), and on this to flow the glass.

---

* A paper read before the Society of Arts on January 21st.

The difference in effect of these two methods is very striking; comparable in terms of water-colour painting to the use on the one hand of transparent tints, on the other of body colour. In the first instance, the brilliancy of the hues and the subtlety of the gradations depend upon the whiteness of your paper: that is, the paper is your highest light, and every tint you lay on it is so much diminution of its brilliancy. So with the slip-faced tile, the white porcelain face is your highest light, and the more brilliantly white it is the more brilliant show the colours of your stained glass upon it; it is the light reflected from the ground behind the glass that brings out the glory and the splendour of the dyes. So it is, precisely, with transparent enamel-work on metal: the more brilliant the ground, the richer and more beautiful the enamel.

With painting in body colours the nature and colour of the ground are unimportant—brown paper will do: the brilliancy of the finished effect depends upon the purity of your white paint. So with opaque enamels, whether upon metal or terra-cotta, the brilliancy must be in the glass itself; the ground contributes nothing to the effect.

The Difficulties of the Glass Face.

The glass face to the tile is one of the difficulties in tile manufacture. It has to be melted on the tile, brought to a viscid state like treacle, and by rights both the glass and the terra-cotta should contract equally on cooling. But they do not; and the addition of a white-ware slip complicates matters. Consequently cracks, generally minute but sometimes serious, occur in the glaze – known in the trade as "crazing" —and may be classed under two heads: those that, occurring in the thickness of the film, still do not actually split it, and those that really divide the glaze, and in consequence expose the body of the tile to the elements.

In many cases the "crazing" (where the cracks do not come through the glaze) adds a quality and charm to the tile. The walls of the fissures on either side slope at an angle, and catch and reflect the light, giving a lustre and a sparkle to the tile. But where the "crazing" is thorough, it is an evil, for it renders the tile unfit for use if exposed to the weather, and even for internal use the beauty of the tile is gradually dimmed, because the cracks in time get filled up with a fine siltage of dirt, and the effect is that of a black cobweb sullying the surface.

Tiles used Externally.

The question of using tiles externally is made very difficult by the doubtful behaviour of the tiles themselves. It is a common sight to mark great patches on walls, where tiles have been and have dropped off—to find them cracked and discoloured. The Underground Railway here is painfully rich in examples of their failure, and I note that the linings in the Two-penny Tube are beginning to discolour. Wet, followed by frost, with an imperfect key for fastening at the back, accounts for the downfall in most cases, whilst the impure atmosphere of London endeavours to discolour everything that it cannot corrode.

In Mr. William De Morgan's opinion, tiles made on the "dry" system—*i.e.*, of clay ground dry, and compressed into shape by hydraulic pressure—are unable to withstand the action of frost when damp. The particles are in such a juxtaposition that the tile is soon saturated with moisture, and when this crystallises there is no room for the expansion of the water, and consequently the ice breaks up the tile; whereas, by the "wet" system, when the clay dust is mixed with water and pugged and variously handled before it is dry enough to go into the oven, the disposition of the particles of clay allows for some expansion of the moisture that has soaked in, which enables the ice to be formed without doing damage to the tile or its cement backing.

Fixing and Joints.

Fixing is often imperfectly done, and unless the fixing is perfect—that is to say, absolutely solid over the whole area of the back of the tile—its detachment is only a matter of time. Tiles made by the "dry" process keep very true in shape throughout all the steps in their preparation (which is by no means the case with those made by the "wet" process), and this accuracy makes their fixing much easier; and when a wall is being tile-plated with a view to protection from the weather or reflecting the maximum of light, a close joint is a desideratum. Too much stress however, I think, is generally laid upon this fine joint and even surface, and the tile-work is apt to look tired and mechanical in consequence.

We lose much of the inherent qualities of our materials in our attempt to secure an excellence that really does no justice to them, and which has as its chief merit that it saves labour and ministers to our convenience.

Of Necessaries and Luxuries.

Now, as regards the necessaries of our lives, these be great and real excellences. To be able to build a wall rapidly and well with bricks that can be equably and truly laid, set in mortar, mixed, and mixed most efficiently, in a mortar mill—is a true convenience, and all thought to that end is thought worthily expended.

But when we come to the luxuries, that is another matter. If you cannot afford to have them done well, why have them at all? It is their excellence that is the justification of their expenditure. And these not quite first-class luxuries defeat their own ends. They are not luxuries unless they amuse and interest us—and how can the blind fingering of a machine tell us of anything beyond its inhuman perfection?

Compare a slab of marble, hand-polished, with one that has been polished by machinery. In the first instance, the surface is full of life and movement; the light falls on its tiny depressions and irregularities, awakening wayward reflections, strengthening and palliating its colours, developing its lustres and translucencies, so that it becomes rich in story as well as in hue. In the other there is the dead level of polished surface, unassailably perfect, but, comparatively speaking, uninteresting. The life and vivacity of the marble are gone; it is merely a polished record, with the pleasant part of its individuality rubbed away into a wearisome uniformity.

So it is with the machine-made wood-panelling with which we decorate our rooms and halls. From lack of any other special qualities its mechanical excellence becomes an offence, and we hang pictures on it and back furniture up against it to mitigate and interrupt its exasperating uniformity.

So with mosaic work. To keep the tesseræ equal and to set them all to one level face is to renounce the great quality of life in one's work and to throw away much that constitutes the charm of the material.

With tile-work the same holds good. A great sheet of exact-shaped tiles, with dead true faces, irreproachably fixed on a dead straight wall (such as one sees at the Wallace Gallery, Hertford House), is sad miprision of the qualities of the material. The want of thought in the arrangement, the presence of mechanism both in the design and the facture (I can hardly use the word *manu*facture, for the hands only guide, they do not make) makes the result a bore and oppressive from the consciousness that it must have been expensive.

What Modern Tiles should be.

That all tiles should be made by the wet process and all be hand-painted is asking, in these days of economical production, more than the circumstances demand; but we might narrow our requirements down to these few particulars, and refuse to allow ourselves to be tempted to enlarge them: that all tiles should have a sufficient key for fixing; that they should be coated with a glaze that protects them from injury by dirt, acid or attrition; that those which are to be used for external purposes should be able to withstand the weather; and that when a printed pattern has to be on the face, that pattern should be of a very simple character, so that its mechanical repetition may be as little tiresome as possible.

In firing a batch of tiles there are generally some variations in the intensity of the colours, &c.; and where the pattern is very simple these discrepancies become fairly marked, and when judiciously assorted help to alleviate the regularity of the printed design.

There are various shifts that may be legitimately used to temper the exorbitancy of hand-labour, such as stencils, printed outlines, and so forth, but the cloven hoof is apt to peep out from amongst them; and the larger the area of repetition the more marked becomes the mechanical regularity of the design. A tile used in a single series down the side of a grate hardly betrays the method of its colouring, but a square yard of them blurts out the story beyond any possibility of suppression or disguise.

Where cost is a consideration and a large quantity of space is to be covered, use plain coloured tiles, and encourage such processes as exhibit the humours and behaviour of the kiln. The glory of a tile is its colour—the pattern is little more than a set of pegs on which to hang these colours; and to cripple one's effect by unnecessary care upon the skeletons of one's figures of beauty is a miserable misapplication of force.

So much, then, as specification of the tile from the decorator's point of view, and of the chemistry of its clays, of its glass, and the methods of handling and firing, I shall not here concern myself; but with the application of the finished article, and that not so much from the utilitarian point of view as from the decorative.

It will be as well, I think, to glance briefly at what has been done in the past, and at examples of what are acknowledged to be masterpieces in the way of tile-work when the art of tile-making and tile-using was at its height. To do this at all adequately is out of the question on this occasion, and it is only by severe and reluctant pruning that I can contain myself within reasonable limits.

Egyptian Work.

I must begin with Egypt because they began first. They discovered a stone that would stand glazing, and they used glazed wall-decoration extensively. The Tell-el-Yahoudi plaques are to all intents and purposes wall-tiles, and their date is 1400 B.C., and Dr. Flinders Petrie has discovered glazed wall-tiles of a still earlier date amongst the ruins of the palace erected by Ku-en-aten in his newly-founded capital. The colours mostly have disappeared owing to the action of the damp during the centuries wherein they lay buried. When the Egyptians used polychrome decoration on their plaques the different colours were let into the object, making it a kind of tile mosaic—not painting, as in a picture, on the surface.

The Discoveries at Susa

mark an advance in the art of wall-decoration. During the Achæmenian dynasty the royal palace had its walls adorned with panels of painted plaques, but these were rather bricks than tiles, and the methods employed were derived from the glazed bricks employed in the architecture of the Babylonian and Assyrian empires. The walls were built of light grey and light rose unglazed bricks ranged somewhat like the walls of the Ducal Palace of Venice, whilst the ornamented parts, which were the portals and great entrance staircases, were in enamelled terra-cotta bricks, the colours being separated by what appears to be a vitreous wall, something after the manner of the metal walls of cloisonné enamels.

Darius gave up the use of terra-cotta and employed a kind of concrete for his bricks, because he found the enamel wore better on the latter.

Ecbatana, with its Walls.

From Susa 'tis but a short step into Persia and that amazing entity, Persian art. In Mesopotamia the Medes built the town of Ecbatana. Up the sides of a steep hill rose the seven circular walls, one inside the other, enfolding the treasury and the king's palace. The outer wall was of immense diameter, and the terraces enclosed by each ring carried collections of country houses with small farms and gardens attached, rather than the suburb buildings to which we are accustomed.

The city was consecrated to the great powers of the firmament, and the devotion of its founders was registered in the form and colour of its walls. The battlements to the outer wall were white; to the next black; the third scarlet; the fourth blue; the fifth orange. The two last walls had their battlements silvered and gilt.

This profusion of colour and metal-work strikes us as extravagant, even in conception, not to speak of realisation; but in Herodotus's time he was writing of facts well-known to many of his readers who had seen Ninevah and Babylon and the pictured splendour of Egypt.

Amidst this wealth of artificial colour grew up the art of Persia, as we know it, and its influence throughout the past has been very subtle and far-reaching. It has coloured India and the shores of the Mediterranean. It is impossible to look at the Moorish work of North Africa and of Spain and not feel the Persian influence exhibited; nay more, most of the work must have been done by actual Persians carried in the train of Arab conquerors. The art of Byzantium played upon it and probably deeply influenced it, but our knowledge of Byzantine art is at present too imperfect to let us pronounce definitely in this direction. The stream of merchandise that flowed through Persia brought with it samples of the porcelains from far Cathay, and after a certain date Chinese influence on the Persian potter is very perceptible.

In China coloured tiles are largely used in exterior work. The "Porcelain" tower at Nankin (destroyed 1853) was so called because the lowest of nine storeys was covered with glazed brick; the eaves over the balconies were roofed in with green tiles, and the window jambs plated with glazed porcelain modelled in relief.

Tile-Making in the Middle Ages.

In the Middle Ages, and outside the sphere of Persian art, there was tile-making, but the tiles so made were for pavements and later on for roof-coverings. The floor tiles were made glazed, but the glaze soon wore away. Innumerable examples of these abound in England and on the Continent, made, I imagine, to reproduce as well as might be the splendours of the marble pavements abroad about which the pilgrims spoke when they returned from Rome and Byzantium or from their crusades in Paynim lands.

When the revival of letters and classic lore and antique art set in, every craft was touched by its influence, and pottery had its renaissance as well as sculpture. But the tile makers drew their new inspirations, not so much directly from the past, as from Spain, and thus in this roundabout way came under the influence of Persia. The Arabs invaded the peninsula of Spain A.D. 711, and remained there, so far as their influence of the tile trade is concerned, till 1610. The Alhambra was begun in 1272, and the tiles that decorate it are the oldest and most interesting in Spain. Their repute widened, and Spanish tiles spread far and wide; they

PALAZZO S. STEFANO, TAORMINA. DRAWN BY F. HAMILTON JACKSON, R.B.A.

were imported in considerable quantities to Genoa, to Naples, and to the islands westward of the peninsula of Italy, and, in company with the European craftsmen, found a market in India.

Della Robbia: Faenza: Majorca.

During the period of the Renaissance various attempts were made to develop the qualities of glazed ware in the direction of architectural employment, the work of the Della Robbia family being the products perhaps the most generally known. Famous factories were established at Florence, Faenza, Gubbio, and many other places under Italian rule; and under the Spanish in the Balearic Isles, and at Naples. So famous were they that they gave a name to their ware that lasts to this day. Faience is Faenza ware, Majolica is the pottery that comes from Majorca.

In the Spanish Peninsula the Renaissance found a special state of affairs. To the south, in what was once the Sultanate of Cordova, Moorish traditions and Moorish craftsmen still lingered on, distinct from the Christian workers who were absorbing their territory; and these rival potters had occasionally blended, so that, besides the Christian and the Morrisco styles, there was a third style that went by the name of Mudejar. It was not till the time of the Great Emperor Charles that the influence of the Renaissance began to show on Spanish work—the painted tiles date from the sixteenth century. Talavera was then the famous emporium, and its goods supplied the country, Portugal and the Far East.

In England glazed plaques, other than paving tiles, are rare. There is an interesting specimen in Lingfield Church, Surrey, an effigy of the time of Henry VIII. in glazed tiles. The figure is incised on a rather coarse red clay covered with a greenish glaze now much worn away. It is supposed, however, that the tiles are of Flemish origin. Similar instances of sepulchral portraiture are fairly common in France.

Tile Pictures.

By the time we are reaching the sixteenth century tiles in Europe—except for pavings and skirtings—are ceasing to be architectural adjuncts, and becoming—or trying to become—more and more tile pictures. It was the flood-tide of the painters and painters who prided themselves on their versatility. Every material was pressed into their service; mosaics, stained glass, tiles, pots, plates and dishes—all were to come out as pictures regardless of the qualifications and the limitations of the material.

In Spain, the Spanish Netherlands and the two Sicilies this picture-painting was taken light-heartedly; the humours of the material were allowed to have their say, and there is a general air of not being on your oath in the treatment of these panels. If you recall the subject of a set of Dutch tiles, you will see a kind of ease in the handling and a liberal acceptance of the imperfections of the ware altogether different to the tense serious treatment of a Maestro Giorgio tazza. The result is that these (to use the loose and inaccurate but generally accepted appellation) Dutch and Spanish tiles persist to this day as living things, whilst the solemn works of art are to be found now only in museums; and we can observe how hopelessly dead the art of them has become by the imitations that are being here and there manufactured.

These finished picture-tiles fulfilled no real want; and as soon as the great burst of enthusiastic appreciation of all forms of craft was over, and the wave of studio excellence abated, they dropped out of circulation. Nobody would have of such things any but of the very best, and the very best were not being made Even the other, more homely, efforts shared in this discouragement and soon sank to a serviceable level, such as lining dark walls and those services that were likely to get discoloured by smoke and dirt; and on these terms they are made and used to this day.

The high standard of draughtsmanship and design had this moral disadvantage, that the artist, to gain this excellence, had to devote his whole force and attention to the pictorial side of his craft, and so became divorced from his material. The tile was no longer treated on its own merits, and its decoration evolved therefrom, but as a field for the painter's display, and to secure effects which, though proper and natural in frescos and easel pictures, are foreign to the nature of a tile, and can only be exported (and then but partially) by the utmost technical ability.

"The Changeless East."

In the East and that part of Europe under Persian influence—as regards the potter's craft—the aim was different. The qualities of the clays and glass were accepted as the basis for development and improvement, and all advance, both in the substance and the technique, was evolved from the tile itself. Nor was the standard pitched either too rigidly or on too high a plane. The ideal was not beyond the reach of the craftsman, and there was no thought of the presence of some superior imported personage who should invest with the garniture of Art the product of the potter's labour; and yet, on those terms, we have examples of consummate work—supreme in technique and in beauty. And this art is still alive, and if it could be left undisturbed would go on quietly fulfilling its purpose.

Unfortunately the restless activity of modern life, with its eager but ignorant appreciation of foreign work, is battering at its door, and we are all busied by our patronage to change "the changeless East."

European—and I am afraid English—influence has, in its blind admiration for the art of Japan, ruined it. It set up a huge and feverish demand, and the Japanese at once set themselves in haste to satisfy it. Other nations in the East are not so mercurial, and consequently have not been so much affected, but they have not been uninfluenced. Both India and Persia, not to speak of other countries, have set themselves to serve the British markets and to conform to British standards. It may be inevitable: it is certainly disastrous. It is sad to think how, with all our good intentions, destructive we are of all those qualities we talk so glibly about—destructive because we are ignorant of what is the essence and purpose of the qualities we call Beauty and Art. At this moment we are not agreed as to what constitutes beauty and what is the function of art; and in our perplexity, whilst attempting to preserve and enlarge the influence of beauty, we do actually eliminate it, whilst we are agreed to transfer art from the practical side of life and to view it as a kind of varnish which only the cultured can acquire and the leisured enjoy.

During the past century we worked ourselves up to a consciousness of the beauty of the works of the Middle Ages in England, our Gothic monuments in especial. We set to work to preserve these beauties, and not knowing wherein they consisted we replaced them with restorations; consequently, nearly all of the chief examples and an immense number of the small are examples no longer. In place of the original, with its history and its beauties, we have a replica which is a modern and silent forgery.

An Instance of Modernism.

Another common instance of ignoring what constitutes the actual charm and beauty of a thing is when some traveller discovers a little spot that has been left untouched by the modern excursionist. Struck with its peace, and the beauty that comes from centuries of quiet contention with and mastery over Nature, and anxious to share his discoveries with others, and thus add to their happiness, he shouts aloud in the highways and market-places the beauty of the village he has found and the simple content of its inhabitants. The ring of enthusiasm in his voice reaches many ears. Next year the village is invaded. A toad-stool growth of cheap lodging-houses springs up, and attractions (so-called) are constructed. The railway sprouts out a branch line, and a station is dumped down cheek by jowl beside the church. The place is now easily accessible, and hundreds can now enjoy the refreshing solitude and idyllic simplicity of the place. Only the solitude and simplicity are gone. So with our improved methods of transit, our facilities of commerce, and our demands, too important to be disregarded and too urgent to be properly executed, we have brought Oriental wares within reach of the humblest; but the beauty and excellence of the stuff is fast disappearing.

Let us review some examples of the architectural application of enamelled ware in times before the advent of the railway and the influence of the connoisseur was less universally diffused.

(A fine series of lantern slides, obtained from the South Kensington authorities, were at this juncture thrown on the screen, illustrating examples in Persia, Turkey, Spain and other countries.)

The Function of Tiles.

And now, what is the moral of all this? One thing that can hardly have escaped notice is the nature of the country in which the examples that you have seen occur. Both in Persia, Tunis and in the Spanish Sierras we are in the presence of arid wastes. Outside the towns there are no trees, no pasture. There is the blue sky over us—but, till twilight, too blinding for the eye to contemplate. No doubt there is a colour in the vault of night that can scarcely be imagined by those that have not seen it; but, speaking generally, there is no colour about these cities but what is of man's nurture or manufacture. The spring brings a flush of blossom and a short-lived wealth of verdure—enough to exemplify what luxuriance of colour means. But for the greater part of the year the landscape is a sober drab affair, with little moisture in the atmosphere to temper the brilliancy of the sunshine. The great function of these enamelled tiles, then, was to catch the fleeting glories of the fields and gardens, and, Orpheus-like, to fix them as "a lasting spring." Both by their design and their colour they recall the starry meads and their wondrous varieties of hues and the lush luxuriance of their verdure.

In the Persian work this is more directly pictured than in the Spanish; but in both the instinct is to secure, by carpets, embroideries, tiles and stained glass, an entourage of colour.

Colour in Country and Town.

In this country colour is perennial with us. It has its tides, its ebbs and flows, but even at its greatest ebb we are encircled with tender russet and purple tints from the woodlands and from the ploughed fields; the pastures keep a greenness; the hedgerows an intricacy of innumerable tints; the hillsides are shaggy with copse wood, and fledged with pines; and sheets of water reflect in intensified colours the vegetation that surrounds their margins.

But it is otherwise in our large and crowded towns; there Nature's restless activities are confined in space and checked in growth. A film of grime reduces the green of summer to an inky grey, and obscures and sullies the yellow of decay, so that we view the complete ruin of the foliage as a desirable riddance, and are thankful to have the fallen leaves swept up and consumed as promptly as possible.

For half the year our city is the colour of a dirty cobweb, and the only refreshment the eye gets is in the glimpses of the sky overhead, the shop windows and the hoardings; these last mark the hunger for colour significantly.

We want colour in our streets; we have tried for it by using coloured building materials, paint, creepers, and flowers in window-boxes. But these ventures are generally disconnected attempts, and so are on too small a scale to make any distinct effect, and owing to the nature of the materials they soon sink back into the general dinginess of the surroundings.

A Plea for the Use of Tiles in Streets.

Why not plate your building with tiles? I do not suggest that a man should veneer his vertical section of a street-side that serves him as his house, and let his neighbour on either side follow or not his novel start, because colour to be effective in such circumstances must be in broad masses.

I should like to see whole streets treated in permanent colour, and please myself with the hope that some day they may be so, but as a beginning in so bold an experiment I should like to see the scheme tried on a detached building, standing free and with some trees about it, or a public building of such a frontage as should be sufficient to display a large plain mass of wall-surface. We have tried spots and panels of colour here and there in our streets already, and they have failed from the timidity of their employment and the insufficiency of their area. The colour must be laid on in a broad bold mass, and pattern used only sparingly, if at all. The windows and other openings should occur in a field of plain colour, or some simple chequer or trellised diaper, and the limits of the tiling should be bounded by bands and trimmings of glazed terra-cotta. I specify glazed terra-cotta, because in building you must not mix perishable and imperishable materials together. Whilst the one is toning, softening and decaying under the blunting hand of Time, the other is merely getting dirty; and each time the front of the house is cleaned the tiles come up as fresh and bright as on the day they were fixed, whilst the corroded framework must remain with the grime that age has brought it.

This permanence is not so great an evil as at first appears. Much, say one-third, of a house-front consists in any case of imperishable materials, such as the glass windows and the woodwork, which are renewed periodically with coats of paint; and whilst the remainder of the house is toning into a dingy uniformity, the harmony of the frontage is every few years disturbed by the freshened appearance, under the painters' hands, of the parts required by the covenants of the lease, and thus making of the harmony a painful discord.

It is true that where the materials are all indestructible the kindly agency of Time can play no part, the building is never any better than when it leaves the contractors' hands, except for the history that gradually humanises its walls; but this view of the ameliorating power of Time belongs to our timid age—the age not of creation but of selection—and is by no means a healthy one. We are afraid to risk anything, and why? Because we are so self-conscious, because we are so eaten up with our sense of responsibility. Not so came the models which we copy into being, although at this moment the style of the past most in vogue is perhaps the most self-conscious that we could have chosen, and (for this follows) the one that is the most disdainful in its refusal of colour.

Work done in Youth.

The love of colour and the power to apply it is characteristic of youth—of the youth of nations as well as individuals. The best (and by that I mean the most inspired) work is done in youth, and the colour then is the richest and most eloquent; though some there be, like Gian Bellini, or to come nearer home, Mr. Watts, who retain their colour faculty right on into old age.

In youth a nation has the courage to court failure, or rather to regard it as a passing circumstance, in its attempt to grasp the ideal. For what to them was failure but the stepping-stone to new effort? So much experience brought to them so much new knowledge and suggested so many fresh possibilities. Not only the science of architecture but the beauty which is the cream and bloom of science, grew up from the careful observation of building disasters, and the invention of expedients that might obviate their recurrence. The conditions of the time and the temper of the people determined the actual forms of the building, so that, for example, we get in one case Classic, in another Gothic architecture, but these styles were living only so long as failure was allowed to be possible and experiments encouraged. When that ceased the art of architecture became a recapitulation of past examples, the science their reconstruction or adaption.

Arguments for the General Use of Tiles;

Why should we fear to cover whole streets in London with coloured tiles? Is there anything to lose? The streets at present are not beautiful, nor are they interesting. The modern ones have no single architectonic quality. There is no general principle of design in them, no uniformity, style, composition, balance; a few good examples of designs occur in the general welter, but they make no effect on the whole, which mainly expresses private obstinacy, tinctured with selfishness. What could be gained by a broad treatment of colour is periodically shown to us when the Quadrant at Piccadilly gets repainted. In that fine sweep we have an idea, unanimity of design, and breadth of colour, and, in consequence, it is one of the pleasantest things one can meet in a tramp through town.

And Objections.

It may be objected that to incrust whole streets with enamelled tiles would be a very expensive business; and that the decoration, whether we liked it or not, would—owing to the cost involved in applying it—be permanent.

I will take the latter objection first. It would, I hope, be permanent. Any scheme, reasonably comprehensive, simple and straightforward, must be a distinct improvement on the present polychromatic distraction, gradually surrendering its distinction under the obliterating coating of London grime. No other surface wears so well. Stone perishes rapidly. Brick and terra-cotta get incurably befouled. Marble requires frequent repolishing. Granite endures, but unless it be polished it also gets very filthy. But a good glazed tile, glazed brick or faïence, should be as durable as a plate-glass window, unaffected by the wildest acids that infest our atmosphere.

Then as to cost. Of course, tiles by the acre come expensive. But there is another side to the matter that we may well consider. At present our buildings, in order to get the contrasts of light and shade—colour, in short—are covered with ornamental features, such as mouldings, pilasters, window trimmings, cornices, balustrades, and similar architectural upholstery, and adorned generally with a profusion of inferior carving. Now, although all this architectural frippery is pretty cheap stuff, considering; still, it does cost money, and by the use of colour we can dispense with the bulk of it. The projecting cornices and sills, the carving, and features generally, form so many shelves and nooks for the dust, dirt, products of coal combustion, and the unhydrated acids enveloped in them. The rain comes and washes the collected dirt against the brickwork, whilst the liquid acids proceed to eat away the stone. Besides, these big projecting cornices are for the purpose of casting deep shadows—the very last things of all that we want in our streets.

In tile-work we can reproduce this effect and count upon its loyal service, whereas in our stonework the effects of light get reversed by the soot, our high lights become the deepest blacks, and the soffits, that should be in shade, are the brightest parts of our mouldings. So that in a colour scheme, with tiles, the value of projections is got by patterns and particular dispositions of tint, and all that is wanted besides the tile-work are slips of some glazed material to act as boundaries to the fields of colour.

There is another virtue in tile-work besides its being imperishable and easily cleaned, and that is, that it is impervious to the elements. There is not the same necessity to load up our girders with thick masonry walls to keep out the weather. A thin glazed skin is sufficient for this purpose, and our walls will be drier and warmer as well. The ordinary brick wall is nearly as thirsty as a sponge-cake, and after a heavy rain-storm there is an immense amount of water to be vapourised before the walls can become dry and warm, and the weight of this water is considerable. With a glazed skin, beyond the comfort of unchanging temperature, so much firing to dispel water will be saved. Moreover, the rain, instead of dirtying the house, will help to clean it, and after each shower the bulk of the filth, disease germs and acids will be washed into the drains and be got rid of comfortably.

But there is more to be done with tiles in the way of external decoration than merely to put them on the fronts of buildings. There are bridges, walls and fountains to be considered.

Glazed brick makes an appropriate casing to the concrete arches of our modern bridges, and the spandrels might be most effectively treated with fine civic heraldry executed in tiles.

A Scheme for Improving Trafalgar Square.

Then as to our public places. Take Trafalgar Square as an instance. At present it is an arid waste, grey and ineffective, with various disconsolate grimy black statues attempting to ignore the presence of the two steaming fountains which mark significantly the proximity of St. Martin's baths and washhouses.

Let us imagine it taken in hand and made to serve some pleasant and and useful purpose, and, so far as we can, beautiful. We will begin by reducing the inordinate size of the basins to the fountains, and lining them with turquoise blue tiles, and by stipulating that for the future the fountains shall spout clear water. We lay the whole of the area, except a fringe to the south of the necessary paths, which shall be of Purbeck stone, with turf, and jealously keep the hoof of the loafer from off it. The statues shall be cleaned up and either kept clean by frequent scrubbing, or gilded. Gordon's statue should be moved nearer to the north wall, and the number of future statues permissible and their positions at once determined, so as to present an intelligible scheme: the wall serving for a background. This wall we will treat for the most part in plain colour, so as to form a quiet backing to the statues; but beneath the parapet we will have a row of hatchments, the arms of those who have done good service to the State and who were connected with that neighbourhood. Beyond and above this base of colour rises the National Gallery, made the richer by this coloured setting.

At present we quite waste our statues by the inappropriateness of the sites chosen for them. Standing in the midst of the confusion and turmoil of our crowded streets, they form pathetic objects, helpless in the torrent of the traffic, or else they are stranded against some building and absorbed in the conflicting detail of their background. The monument is made regardless of the site; and as nobody in authority seems to care, it is dumped down on the first convenient spot handy, where it may divide with overshadowing lamp-posts the duty of dividing the traffic and imprisoning the pedestrian.

The Internal Use of Tiles.

Of the internal application of tiles there is not much for me to say. A good deal has been done in this direction of a very interesting description, but by the nature of the case most of the examples were conditioned by special circumstances.

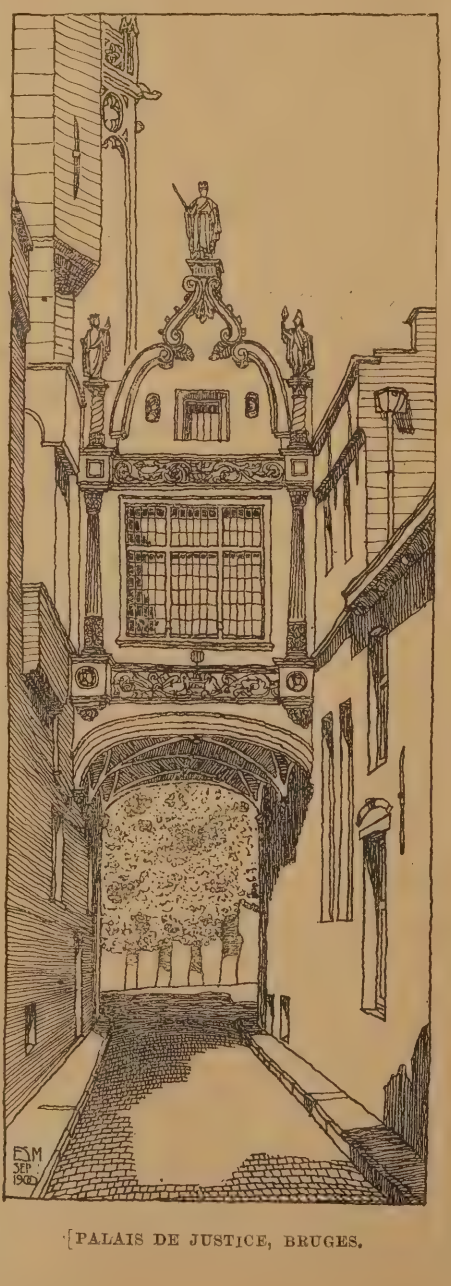
An early example of the decorative treatment of tile-work can be seen in the refreshment and grill rooms at the South Kensington Museum; and examples of Mr. Waterhouse's treatment of tiles may be seen in his various public buildings, banks and insurance offices. Mr. Butterfield, in several of his London churches, was also a pioneer in this species of decoration, though the tiles he used were for the most part those misnamed encaustic rather than the enamelled ones. Subsequently Mr. Aitchison built the Arab Hall for Lord Leighton, using for the most part the collection of old Oriental tiles that Lord Leighton had procured, and decorating the staircase hall with mainly new ones, but in admirable sympathy with the old. Outside the specimens of old tiles in the British and South Kensington Museums, a more beautiful example of Persian tiling is not to be seen in England. Leighton House also helps to dissipate the rather general idea that a tile-surface must look cold and uncomfortable, for nothing can exceed the air of protection and richness that even the plain tiles on the staircase give.

Since then the practice of using tiles for internal decoration has increased immensely, though more in what are known as business premises than in private residences. It is, consequently, for the external use of colour decoration that I would specially plead, and, for the decoration to be of a permanent kind, got either by enamelled tiles, glazed faïence or mosaic. The French have already made some excursions into this field, notably at the Paris Exhibition, and are still pursuing the subject of building in steel and terra-cotta. It is a matter, I think, of deep regret that at the South Kensington Museum, where so plucky a start was made in using materials that withstand our climate, and carrying them out with so much interest and beauty, there should now be abandonment of their spirited departure instead of development, and that they should have reverted to the tame respectability of stone. One might have hoped that in a new building, for new purposes, and on so large a scale, every opportunity would have been taken to advance one step further the architecture of the present day, and, since the occasion seemed so suitable, to erect an example of coloured architecture. The result of this stony disdain, this proud scholarship of our streets, is that we cannot live in them. Every evening thousands upon thousands escape by every railway from these masterpieces of correct architecture and superfine sculpture to the shelter of the country, where the earth is green about them and the heaven blue above them. Cannot we make our streets a little more kindly and comforting to those poor prisoners who cannot escape? We have tried mass and form and light and shade; might we not now have an attempt at colour?

A short discussion followed the reading of the foregoing paper. Mr. Lewis F. Day said, with regard to the Spanish work, that it was not realised how all the tile-work in the Alhambra was literally a mosaic of pieces of tiles, which were very soft and were thus able to be cut and filed up into shape. This treatment was also due to the fact that the workers had no means of obtaining various colours on the same tile. When they did arrive at that knowledge they proceeded to imitate those mosaics and produced tiles like them.—Mr. H. H. Statham remarked that wherever bright sunshine was, there bright architecture would be found; and wherever strong colour was used in the architecture, the employment of mouldings became restricted. Whilst agreeing with Mr. Ricardo that a greater use should be made of tiles in this country, he did not very much like the idea of a street architecture of glazed surfaces: and he made the practical objection which arose from the fact that different ownership of buildings in the same street would result in different treatments, and he was dubious of the means for harmonizing them. Perhaps, he suggested, the district surveyor of the future would, among his other qualifications, be required to possess an eye for colour, so that he might sit in judgment on any new scheme that came within his sphere?—Mr. Aumonier, who entirely supported the lecturer's opinions, failed to appreciate Mr. Statham's objection, remarking that in a garden of many flowers, though the colours were innumerable, yet there was always harmony and not discord.—Mr. Paul Waterhouse (who presided over the meeting) spoke of the use of lead in glazing, and drew attention to the battle which the Home Office was waging with manufacturers. By an increased use of tiles architects might be increasing the great moral evil attendant on lead-glazing, but more than one manufacturer had shown that it was possible to obtain equally good results without the use of lead, and their methods deserved our support

INDIAN ARCHITECTURE.

INDIAN architecture does not receive the attention which it deserves, considering what splendid buildings are included in that style. In this connection it is interesting to refer to the annual report of the Archæological Survey of Western India. Mr. Henry Cousins, the superintendent of the department, says of his visit to Mount Abu, which lies near the south-west extremity of the Aravalli range that divides eastern from western Rajputana:—The plateau extends some fourteen miles north and south, while in breadth it varies from two to four miles. Towards the southern end lies the civil station. About a mile to the north are the Dilwara temples. This group consists of four principal temples, each with its subsidiary shrines and corridors, contained within its own enclosed quadrangle, as is the usual arrangement with the Jains. They are constructed almost wholly of white marble, quarried in the plains below, and brought up miles of rugged hillside by some means we are now altogether ignorant of. The amount of ornamental detail spread over these shrines in the minutely-carved decoration of ceilings, pillars, doorways, panels and niches is simply marvellous; the crisp, thin, translucent shell-like treatment of the marble surpasses anything seen elsewhere, and some of the designs are dreams of beauty. Amongst all this lavish display from the sculptor's chisel, the two great domical ceilings of the halls of Vimala Sah's and Tejahpala's temples attract most notice and come in for most praise. Within each of these great ceilings, arranged in a circle, are sixteen female bracket figures, goddesses known as the sixteen *Vidya-devis.* There are some curious figures in the corners of some of the smaller ceilings, half-human, half-bird, with magnificent florid tails. These are *Gandharvas*, or celestial musicians, with their pipes and cymbals. In the older temple—that of Vimala Sah, which, an inscription tells us, was built in A.D. 1032—the pillars of the hall are of the same type as those in the hall of the Temple of Ambarnatha near Kalyan, which is dated A.D. 1060, and are all of a uniform pattern. But in the Temple of Tejahpala, built about 200 years later, the architects had lost the early vigour of well-established forms; they allowed themselves a freer fancy, and we find them indulging in very nondescript and whimsical designs. The general plan of the later temple has been copied from the earlier, and so has the great dome in all save the bolder innovation of the heavy massive pendant in the centre. Though the detail work of these temples is exquisite, and the designs are not only novel in their treatment but extremely pleasing to the eye, yet the setting of the work is at fault. The general outlines of the buildings are not in the best proportions. Such large domes as these two principal ones of Vimala Sah's and Tejahpala's temples are set too squat; they require greater height. Although the interior of the temples and courtyards are kept scrupulously clean, their surroundings are certainly not so, and the filthiness in some places is a disgrace to the Jaina community.



[PALAIS DE JUSTICE, BRUGES.

New Patents.

These patents are open to opposition until February 31st.

1900.—Sewage Purification.—23,412. D. Cameron, 1, Sylvan Road, Pennsylvania; F. J. Commin, 7, Bedford Circus; and A. J. Martin, Bradninch House: all of Exeter. This invention relates to the aëration of the sewage effluent by causing it to fall through the air from the edge of a trough fixed above the filter. Instead of fixed aërators, rotary sprinklers are used, such as are used for watering lawns. The invention also includes improvements in the alternating gear and other details.

Slide-Rule for Timber.—23,627. R. L. Jennings, 114, Colum Road, Cardiff. This rule, which consists of a disc having two rotatable flat rings of brass or aluminium, combines five logarithmic scales for the purpose of quickly computing the measurement weight of deals, flooring boards, &c., and also for cubing timber.

1901.—Cistern Disinfecting Apparatus.—1,833. A. G. O'Brien, Machon Bank, Nether Edge, Sheffield. Above the cistern is fixed a funnel-shaped receiver having a depending tube with a basket at its bottom end (within the cistern). The receiver is filled with a disinfectant in powder form and a charge automatically falls into the basket after each discharge of the cistern, this being effected by a pair of cut-off plates which are attached to and operated by the main lever.

Water Taps.—4,124. F. N. Mackay, Holly Bank, 4, Nicoll Road, Willesden, London, N.W. On the pressure side of the valve-seat the tap is provided with a spring-controlled supplemental valve, which rises and checks the supply to the tap when the main valve is removed. The washer can thus be renewed without necessitating the shutting-off of the water from the main.

Girder Coverings.—5,257. B. Jacquart, South River, Middlesex, New Jersey; and J. F. Booraem, 1, Madison Avenue, New York, U.S.A. The girder is entirely covered by a brick on either side and a bottom brick (preferably enamelled), all interlocking. Similar bricks cover the span.

The following specifications were published on Thursday last, and are open to opposition until March 8th. A summary of the more important of them will be given next week. The name in italics is that of the communicator of the invention.

1901.—32, Cook, guards for wood-working machines. 70, Harris & Hawes, radiators. 361, Shanks & Simpson, lavatories and urinals. 942, Crellin, apparatus for raising, lowering and transporting machinery. 2,098, Thorpe, windows, sliding panels, &c. 2,975, Dewhurst, means for connecting filters, pipes, &c., to taps, 3,348, Pridmore, door-knobs. 4,249, Anderson, cranes. 4,366, Bellamy, Turner & Hardman, safety devices for the trolley poles of electric cars. 14,333, Karfunkelstein, gas soldering irons. 18,032, Spatz, waterproofing and drying walls. 18,677, Dawson, apparatus for detecting leaks in drains and other closed systems of pipes. 19,017, Green, channels and terminals for inspection chambers. 19,683, Schulze, baths. 20,023, Taylor, excavating machines. 20,839, Lepper, taps and cocks. 22,320, Haddan (*Brown Hoisting Machinery Co.*), corrugated material for roofs, walls, &c. 23,404, Kett & Hossenlopp, coverings for the floor openings of lifts.

The Palais de Justice at Bruges is just beyond the cottage at Notre Dame illustrated on p. 409 of this issue. The back view of the building towards the fish-market and canal is the most picturesque. The front is very elaborate, being decorated with gold (the accompanying sketch up the passage between the Hôtel de Ville, by Mr. E. Stanley Mitton, gives one an idea of it). The council-chamber of the magistrates is particularly noteworthy. It is antique (though the rest of the buildings date from 1722), and contains a magnificent oak chimney-piece occupying nearly the whole of one side of the room, and dating back to 1509. On it are carved statues of Charles V., Mary of Burgundy and Maximilian, Charles the Bold and Margaret of York, his third wife, surrounded with coats of arms of Burgundy, Spain, &c. It has also marble bas-reliefs representing the story of Susannah.

Views & Reviews.

Early Christian Art.

This book, written by an American scholar, is a most important contribution to the history of the monuments of the early Church, comprising in its scope all branches of Christian art and archæology. The period covered is from the second to the sixth century inclusive. In this work the author, we think, conclusively shows that the early Christian art was not, as has often been assumed, new and original in its form, produced by the complete dissociation of religious thought and ideals from the Roman; but, like the religious conceptions, was based on the other, the early Christian congregations being no more able to separate themselves from the current thought of their age than we are from this. In course of time the differences in view made the most momentous changes in form, and the importance of studying this early art is to trace its effect in the evolution of the Romanesque and Gothic styles. This book does not, of course, pretend to follow the subject into these later stages, but wisely confines itself to clearing up the illusive ground of the early beginnings, and the author, having unravelled the tangled skein, leaves to others the joining on of the later forms to the now clearly visible ends. Mr. Lowrie, we are thankful to say, is not critical of this rude art, but contents himself with collecting material and presenting it in historical form. The book deals very thoroughly with the wide range which the subject covers, treating of cemeteries; architecture; pictorial art, including paintings, sculpture, mosaics and miniatures; the minor arts; and civil and ecclesiastical dress. In the architectural chapter the author traces the church plan as derived from the plan of a Roman house. It is certain that the earlier meetings must have taken place in houses, but it seems somewhat far-fetched to argue any close connection, seeing how diverse were the plans of actual churches. It would seem that the plan was more a product of the form of ceremonial.

"Christian Art and Archæology," by Walter Lowrie, M.A. London: Macmillan & Co., Ltd., price 10s. 6d.

British Sculpture and Sculptors.

Mr. Spielmann must be congratulated on having seen a want and met it. True, this book is primarily for the public, but of course any book would be of little practical use to a sculptor. The chief purpose of a book on British sculpture is to give interesting biographical details of sculptors and to record their chief works; and it should be made interesting and entertaining to the public appealed to. The illustrations in this book are well reproduced in the majority of cases, though the black backgrounds generally make a piece of sculpture look lifeless and cold. Every living sculptor of note is mentioned. In the introduction several contentious subjects are touched on. Mr. Spielmann thinks that if several colours are applied to sculpture they clash and weaken it, but that a single colour throughout does not decrease from its dignity. If imitative colour is indulged in on a statue, of course the work is at once degraded, as it pretends to be what it is not; but if the work is of decorative character, decorative colour is perfectly justifiable. As long as the colour takes its place in the fulfilment of a logical idea all is satisfactory, and the successfully coloured sculpture is entitled to be held higher in the scale than monochrome, in virtue of its possession of another powerful element.

Stress is laid on the degrading influence of clay-modelling on sculpture in stone or marble, by making the forms plastic rather than glyptic. It is here that we find the traditional architectural sculpture of the Gothic, Roman, Greek and Egyptian periods was superior in some respects, the idea not then being inharmoniously rendered by overpowering the technique. Of course clay is most useful for sketching out, but the difference between glyptic and plastic art must always be borne in mind, and, indeed, in working in metal even the material must rule the forms.

The bane of "Committees" is dealt with vigorously, and should do good. Mr. Spielmann, we are glad to see, recognizes that an architect should control the sculptor where the latter's work is subordinate to the building, and *vice versâ* where the sculpture is monumental and to be supported by the building, but of course the two should closely co-operate. The best work will never be done, however, except by each knowing a good deal of the other's art. Architecture is indeed but sculpture on a large scale, and both must be organic.

"British Sculpture and Sculptors of To-day," by M. H. Spielmann. London: Cassell & Co., Ltd, price 5s.

Egyptian Archæology.

All those interested in Egyptian archæology will find this dictionary a most useful addition to the books on the subject. There is a great fascination in the remains of ancient Egypt, and every year the labours of Prof. Flinders Petrie and others are adding to our knowledge and bringing back to us some conception of that wonderful bygone civilization. To most it has been very difficult to interpret something from such objects as are in the British Museum, by reason of the want of a small dictionary that could be placed in the pocket. This book now accurately fills that want. It is profusely illustrated with small figures giving the hieroglyphs for the words where necessary. We would suggest, however, that a fairly long list of hieroglyphs should be given, as it would save going to other volumes not so easy of reference. The book will undoubtedly be of very great value to those travelling in Egypt.

"A Concise Dictionary of Egyptian Archæology." By M. Brodrick and A. Anderson Morton. London: Methuen & Co., 36, Essex Street, W.C., price 3s. 6d.

MR. HAITÉ ON MODERN DECORATION.

IN the course of the lecture on "Decoration, its Methods and Materials," which he delivered recently to the Northern District of the Institute of British Decorators, in the Museum Galleries of the Manchester School of Art (Mr. J. H. Reynolds, director of the School, occupying the chair), Mr. G. C. Haité said he must assume his audience to be conversant with the lecture delivered by him at Sheffield on November 28th last, when he dealt with the subject of decoration from a historical point of view (reported in our issue for December 4th); and he must also assume that he was addressing an audience of decorators. Trustworthy decorators were very much needed to-day; and it behoved every master-decorator and every workman to make himself trustworthy. There ought to be the desire on the part of every decorator to do better work than his rivals; and such a desire was very laudable. He should always be ready to learn and be open to conviction, but very slow to adopt eccentricities. The connection between architecture and decoration was also of the greatest importance, and decorators should carefully study this relationship. Unfortunately, in many cases of domestic decoration with which one had to deal there was no architecture worthy of the name; and to that extent the decorator had nothing to work upon. This brought one face to face with the fact that the architect often entirely ignored the decorator and his work; and by his influence retarded the progress of decorative art, instead of advancing it, as he should.

There was much that was repulsive to good taste in the misapplication of the principles of form and colour in pictorial and decorative art, in jewellery, and even in advertising posters. It really seemed in the last direction that an official censorship was necessary. It was anomalous that we should have a censorship of plays, for instance, and no supervision of what passed as art in many of our public places. Bad decoration was, however, supposed to entail no consequences. The lecturer pointed out some of the consequences of bad construction in architecture, in engineering and in furniture. It was just as desirable that those who gave expression to bad decorative art should also suffer. Again, while people were willing to take the advice of specialists in most things, almost everyone considered himself a decorative expert. True, there was a small class of people willing to be advised as to what was good for them in matters decorative, but the great majority were not.

Mr. Haité spoke at some considerable length on the principles of ornament. Some persons ridiculed the idea of laws in decoration. Applied art, however, depended on law. The essential principles, underlying everything else, were fitness and beauty. Their application must be fit as to time, fit for the place, fit for the object decorated, and fit as to the medium employed. He enumerated some of the laws which were interpretations of the principles referred to: symmetry, balance, proportion, spacing, subordination, repose, radiation, contrast, repetition, rhythm, &c. Beauty might be defined as a harmonious co-operation of many pleasing qualities.

Decoration was subject to many limitations, and often these limitations were positive advantages. Take, for instance, the Moorish prohibition of the imitation of Nature. As a result of that we had the use of many forms showing very beautiful results. The limitations imposed by lines in lead-light work were an absolute necessity, yet, once recognized, what possibilities arose in their use. In stencilled ornament, the fact of having to use ties imposed certain limitations; yet, when properly employed, ties greatly enhanced the effect of the ornament.

Coming to essentially modern forms of decoration, he said there appeared to be two schools of thought, one of which would prohibit the use of many examples of manufactured goods, believing that the true sphere of the decorator was in the production of ornament in the flat; and the other recognizing that the goods made ready to hand were a product of the time, and their use, as such, quite appropriate. The first idea implied that every executant should be a designer, and he was in favour of this if the men could be found. We must differentiate between a designer and a house-painter, for design required a master-hand. He would urge upon all decorators the desirability of having their own private designs prepared for them by competent designers. Such men could offer great advantages to their clients.

Speaking of the many relief materials now in use, the lecturer pointed out numerous decorative possibilities open to the decorator. These materials were put into his hand in an incomplete state, and left for him to finish. By a wise selection and use of these materials good effects might be produced.

With the aid of a lantern and specially-prepared slides, many suggestive arrangements of these materials were illustrated.

Engineering Notes.

The Electric Light Installation at the Northern Hospital has cost the Metropolitan Asylums Board £11,781 4s. 4d.

The Mission Hall, Rugby, has been fitted with the latest improved hot-water heating apparatus by Messrs. John King, Ltd., engineers, Liverpool.

The Corporation Temporary Hospital, Southport is being warmed and ventilated by means of Shorland's patent double-fronted Manchester stoves with descending smoke flues, supplied by Messrs. E. H. Shorland & Brother, of Manchester.

New Tube Railways.—Three Bills are to be introduced in this Parliamentary session, namely, the London United Electric Railway Bill, the Charing Cross, Hammersmith and District Electric Railway Bill, and the Piccadilly and City Railway (No. 2) Bill, all of which threaten in some way Hyde, St. James's and the Green Parks by proposed tunnels under them. It is feared that the existence of tube railways beneath the surface will cause injury to the flora. It is suggested that the plan of running under the parks is due to a desire to avoid possible claims by owners of buildings, on account of vibration. A Bill will also be promoted this session for the construction of an underground electric railway from the City to Wimbledon. The proposed line will begin within twelve yards of Cannon Street Station, and will pass under the Thames to Southwark, from whence it will proceed, viâ Lambeth and Wandsworth Road, to a point near Clapham Junction. From this district it will run viâ St. John's Hill to Wandsworth, and from thence to its termination at Hartfield Road, Wimbledon.

Shillelagh Water-Supply.—Earl Fitzwilliam has provided at his own expense a water-supply to Shillelagh. Before this the people had much difficulty in getting pure water, several sources having been condemned as dangerous to health.

The Westminster Electric Supply Corporation, Ltd., have reduced the price for energy used for power purposes to half the lighting rate. The rate is now, for the first 4,000 units used in each year, 3d. per unit. For all units used in each year in excess of 4,000, 2d. per unit. These rates are subject to a discount of 8 per cent.

Liverpool's Water Supply.—The Liverpool City Council last week adopted a recommendation by the Water Committee that a second line of pipes be laid between the city and Lake Vyrnwy, in Wales, the chief source of the present water-supply. The work will involve an outlay of £785,000.

The Leith Dock Commission propose to improve the shelter and accessibility of Leith Roads, and at the same time assist the flow of the tidal current, on which the maintenance of the depth depends, by carrying out, at a cost of £135,000, a breakwater 3,770ft. in length along the reef of rock from the south point of Inchkeith, and to remove the Hermit and the Little Hermit rocks, &c. The whole estimated cost of the work amounts to £325,000.

Electric Traction between Tooting and Westminster.—The work of laying the conduit system of electrical traction on the Tooting and Westminster route will be commenced in the middle of March. The contract price is £171,000, and it is hoped that the new cars will be running in about ten months' time. In all probability operations will be started in the southern district. The work will be done in sections, from which the ordinary horse tramway traffic will be diverted until they are completed. Generally speaking, there will be no night operations, which are twice as costly and half as efficient as day work.

Southend Improvements.—The Southend Town Council has sealed an agreement with a syndicate for the construction of a large water chute on the east side of the pier, the rental to be £1,000 per annum. A suggestion has been made for utilising the tide, by means of an extensive inland lake, for generating electricity for driving the tram-cars and lighting the borough and the adjacent towns of Rochford, Shoeburyness and Wakering. There is also another suggestion for constructing a double tunnel about a mile long from the shore end of the pier for continuing the trains to the terminus of the Great Eastern Railway or a station midway connecting the Tilbury and Midland lines.

A New System of Steel Manufacture.—The Frodingham Iron and Steel Co., Lincolnshire, which has successfully worked the open-hearth basic steel-making process for eleven years, have just commenced the working of a 100 tons Talbot continuation process furnace. It is the first of its kind in Europe, and with the exception of a small experimental furnace in America is the only one in the world. The inventor of the furnace is Mr. Benjamin Talbot, a native of Shropshire, who received his preliminary training in England before going to the United States. The principle is a combination of the open hearth worked on the continuous process. The bath of molten metal in the furnace is worked up to a certain point, and then a portion of the steel is poured out, the charge in the furnace being then made up to its normal strength by molten iron taken up in ladles from the adjoining blast furnaces and poured into the furnace. The furnace will be tapped, or, rather, a portion of the steel will be taken from it, at very short periods, probably about every four hours, and this will constitute a very rapid process of manufacture. The furnace is a Wellman tilting furnace fitted with an electric charger. The whole is worked mechanically. There is an electric crane, and even the doors are lifted by hydraulic power. The builders are Messrs. Tannett, Walker & Co., of Leeds.

Scarborough Town Hall.—Application is to be made to the Local Government Board by the Scarborough Corporation for power to borrow £3,075, in addition to the £14,000 already authorised, for the adaption of St. Nicholas House for the purposes of a town hall and public offices.

Law Cases.

Definition of "Adjoining Premises."—The case of *White* v. *Harrow—Harrow* v. *The Marylebone District Property Co.* recently came before the Court of Appeal. The plaintiff White is the lessee of No. 24, High Street, Marylebone, for a term expiring in 1932. In 1899 he demised the house to the defendant Harrow for a term of twenty-one years, and the lease contained a covenant by the lessee that he would not do anything which might "interfere with the quiet enjoyment of any adjoining or neighbouring premises." The Marylebone District Property Co. have acquired an interest in property adjoining No. 24, High Street, and they were proposing to erect thereon some buildings which, as Harrow alleged, would obstruct the access of light hitherto enjoyed by his premises. He accordingly brought an action to restrain the company from building, and White, who is also interested in the company, took proceedings to restrain Harrow from prosecuting his action, on the ground that it constituted a breach of the above-mentioned covenant, and he moved for a stay of proceedings in that action. Their Lordships allowed the appeal. Lord Justice Vaughan Williams said it had been contended that upon the construction of the particular covenant in question the words "adjoining premises" extended not only to buildings which came in physical contact with the demised building, but also to any buildings which were situated near enough to obstruct easements. He could not agree to that construction. He thought that "adjoining" meant "adjoining" in the sense in which the word was used in the London Building Act, 1894.

Clauses in Specifications.—The case of *Hobbs* v. *Turner* recently came before the Court of Appeal. The plaintiff sued the defendant for £27 10s. for metal work supplied for a house which the defendant was having built for him under the supervision of Mr. J. L. Williams as architect. By the contract, which was in the form issued by the R.I.B.A., the builder undertook to do certain portions of the work, and as to the other portions provisional sums were specified. The specification contained this clause: "Provide and fix iron balcony railings to design (allow £50 for this irrespective of carriage, fixing and profit)." In consideration of the sum of £4,700 the builder agreed to execute and complete, subject to the conditions in the schedule to the contract, the works described in the specification. He was not necessarily to execute the whole of the work, but the building owner might get other persons to do certain parts of the work, and as against the builder certain fixed sums only were to be paid out of the lump sum to those persons for that particular class of work. He could only allow as against the builder the fixed sum for each class of work. That being so, clause 28 of the conditions seemed to the Master of the Rolls to contemplate payment for this class of work being made either by the builder or by the building-owner, and the last part was based on the hypothesis that part of the work might be done by the builder and part not done by him, and where any such work was not done by the builder the building-owner would be entitled to hold back the amount specified for that work. This clause was obviously framed upon the footing that the building-owner was liable for this particular class of work. In his (the Master of the Rolls's) opinion, when one looked at the whole of the contract taken together, the proper inference as regarded this particular class of work was that it was intended that the building-owner, and not the builder, should be the principal. If the builder entered into a contract for any of this class of work he might make himself liable to the tradesmen or artist; but, as he was acting under the general scope of the contract, he would be acting as the agent of the building-owner and would create privity of contract between the building-owner and the tradesman or artist. That could only be got rid of by the tradesman or artist contracting with the builder in such a way as to debar himself from resorting to the building-owner. Nothing of that kind occurred here. What happened was that the plaintiff was put into relation with the defendant through the architect, and, though this was not clear, he understood that the order was given to the plaintiff by the architect. It seemed to his Lordship that the initial liability of the defendant in respect of this class of work was established, and that all the parties dealt upon that footing. The judgment of Mr. Justice Kennedy was, therefore, right. Lord Justices Romer and Mathew agreeing, the appeal was dismissed.

THE DOME AS AN ARCHITECTURAL FORM.

THIS was the title of the paper which Prof. Baldwin Brown read before the Edinburgh Architectural Association last Wednesday (Mr. Henry F. Kerr, president, in the chair). The purpose of the paper was to bring into view the general æsthetic character of the dome, and more particularly to vindicate for it a place among the architectural forms suited for a Christian church. The lecturer said that the main characteristic of the dome in general was its embracing uniting quality. Its employment as a mere roof, as in the multiplied domes of later Byzantine churches, such as St. Mark's at Venice, or the series of cupolas along a rectangular aisle, as in churches of the west of France, was not the way to secure all the advantages of that most beautiful and expressive feature. The dome, wherever it appeared, lent distinction to a building, and it had been rightly pronounced to be on the whole the most satisfying to the æsthetic sense of all architectural forms. The real power of the dome was, however, only exhibited when it was made to exercise an influence far beyond the limits subtended by its own circumference, and brought into harmony the complex elements of a sub-divided plan. The Pantheon of Hadrian at Rome, the starting-point of the development of dome-construction in the modern world, completely embraced the spaces of the plan it surmounted, but this plan was not that of a regular unbroken circle. The Christian builders desired to use the dome for their own purposes; but such a plan as that of the Pantheon was not suited for a Christian meeting-house. One of the most interesting chapters in the whole history of architecture was occupied with various experiments made by early Christian architects to adopt the dome to plans suited to the requirements of congregational worship. The efforts to overcome the difficulties which presented themselves were sufficient proof that they recognised the dome as a form not only beautiful in itself but expressive of Christian ideas, and this was a consideration too often lost sight of by the mediævalists of to-day, who, as the discussions connected with the new Liverpool Cathedral had shown, were still dominated by the ideas embodied in the Gothic revival of the first half of the nineteenth century. The efforts referred to were ultimately crowned with success, when the architect of Justinian's Church of Sta. Sophia at Constantinople combined the dome with the rectangular ground plan normal in the Christian meeting-house. It was a curious fact that after Sta. Sophia the planning of domed churches retrograded, and small cupolas were multiplied over the arms and intersection of Greek crosses, or distributed like the five on a dominoe over a square. Some later Turkish mosques seemed, however, to show a revival of the Sta. Sophia tradition. Meanwhile other points of interest in the history of dome construction emerged, the chief of which was the employment of the cupola in later Byzantine architecture, and again at the Renaissance as an external rather than an internal feature. There was a fine field open to the efforts of the modern designer in the direction indicated by Sta. Sophia. The triapsidal plan, that could be effectively combined with a central dome, offered opportunities for experiments, and these might result in a centralised church for congregational purposes, free from the suggestion of mystical sacerdotalism which clung to the mediæval fane, and recalling the glories of some of the early Christian domed structures that had passed away. If architectural students who went to Cologne would shorten their stay in the Gothic Cathedral, and spend more time in St. Mary of the Capitol or the Apostles' Church, some fresh and promising elements might be imparted into the church architecture of the day.

Enquiries Answered.

The services of a large staff of experts are at the disposal of readers who require information on architectural, constructional or legal matters. Questions should in all cases be addressed to the Editor. The querist's name and address must always be given, not necessarily for publication.

Claim for Alleged Violation of Contract.

NEWPORT, MON.—NAIVETE writes: "A accepts tender by B (of £36) to execute some alterations to A's premises. A complains that parts of the work are not done according to specification, and also informs B of certain damage to his premises. B in reply sends A an account and requests a cheque in settlement. A sends a cheque for two-thirds of the amount of B's tender and points out the work not done according to specification. B contends he has finished the work, but, as regards the damage, offers £ as an indemnity. Can A legally claim from B the cost of finishing the work and repairing the damage done? Also, can A legally claim reasonable expenses in preparing professional and other evidence? Can B claim the full amount of his tender?"

I am of the opinion that a binding contract exists between A and B—B to do certain work according to certain plans and specifications furnished him by A, and A to pay him when the work was completed according to these specifications. You do not state what is the damage alleged to have been done to A's premises by B, nor the alternatives he proposes for B's acceptance; therefore I am unable to say whether or not they are reasonable. B, on the other hand, alleges that he has finished the work according to contract, and offers a certain sum to A to cover the damage. For the reasons above stated I am unable to say whether this offer is reasonable or not; neither is it stated whether or not B's offer was made "without prejudice." The question as to whether A can, in the event of B refusing or neglecting to complete the work, complete it himself depends on the question of fact whether or not the work as it stands is complete according to the contract. No data has been given which would enable me to form an opinion on this part. If the work is not complete, and if the time (if any) fixed for completing it has expired, or, in the event of no time being fixed, after the lapse of a reasonable time—and in either case after due notice to B of A's intention—A can, in my opinion, complete the work himself and afterwards recover the amount from B or deduct it from the balance payable to B in his hand. I gather from the facts submitted that B's offer was *not* in respect to damage for non-completion of the contract but was offered in liquidation of damage caused by him to A's property irrespective of the contract. If A's contention that the work is unfinished is upheld in court he will of course be entitled to all costs of suit. From the amount of B's tender I gather the amount in dispute to be small, and suppose A will proceed in the county court; but before incurring expense for preparing professional and other evidence he should consult a solicitor.

W. JOHNSON-ROBERTS.

Book on Ventilation and Heating.

BIRMINGHAM.—G. H. L. writes: "What book would you recommend as trustworthy and practical on hot-water supply to domestic buildings; and also what book on heating and ventilation? I do not want a small text-book."

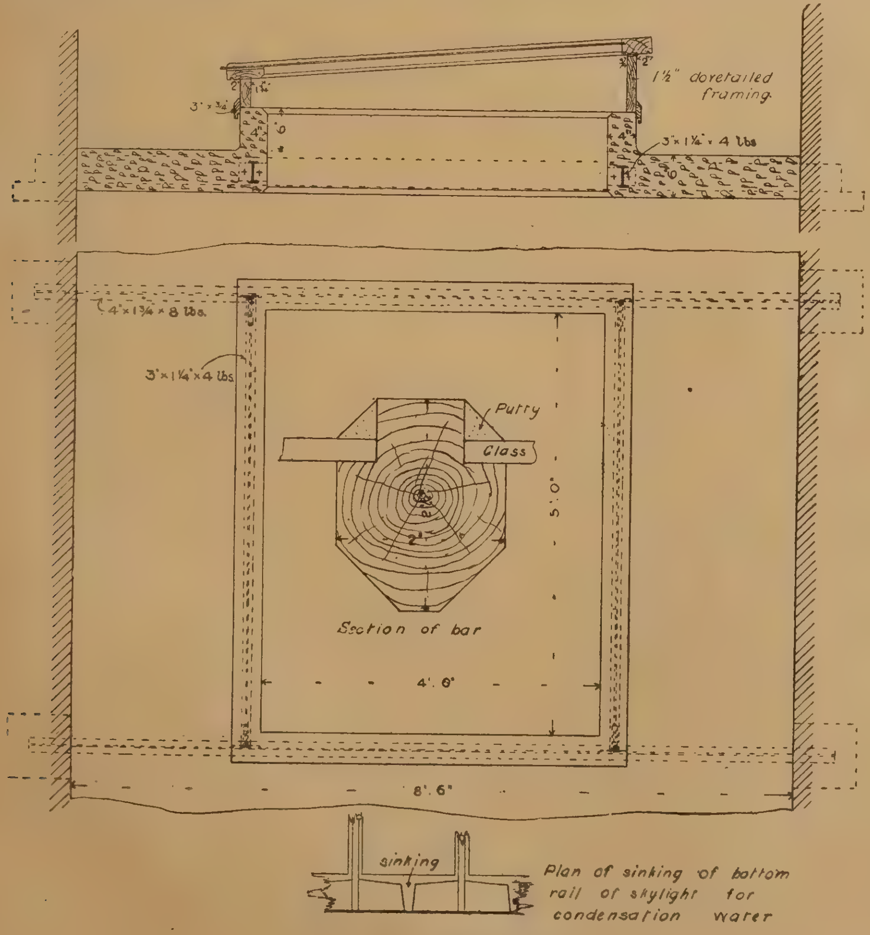
"Ventilation and Heating," by J. S. Billings (B. T. Batsford, 25s. nett).

Skylight on Cement Flat.

LONDON, N.—QUERIST writes: "Please give details of a skylight on a cement flat."

The accompanying illustration shows a cheap skylight arranged as requested on cement flat. The larger rolled joists should be about 5ft. centre to centre throughout, but may be widened a trifle at the skylight. The concrete should be, say, 5 ballast to 1 of cement, and the centering should remain at least a fortnight after completion.

HENRY ADAMS.



SKYLIGHT ON CEMENT FLAT.

Powers of Urban Council to Enforce Repairs.

FLEET.—DOUBTFUL writes: "Has the local authority the power to compel owners to close property and still levy rates on it? Having some old dwellings in the suburbs of an urban district, I was induced to sign a form in which I agreed to pay the local rates (reduced), whether the houses were occupied or not. I have now received a notice under the provisions of the Public Health Act, 1875, and the Housing of the Working Classes Act, 1890, to do certain repairs (not stated), or am threatened with proceedings. Supposing I elect to close the houses, would I still be liable for the rates, or would it be necessary to pull the property down entirely to get rid of this incubus?"

Owing to the fact that you signed an agreement to pay rates, whether your premises were let or unlet, in consideration of being charged a reduced rate, you are placed in a very awkward position. As far as I can see your sole defence is that the premises have ceased to be houses, *i.e.* habitable houses, and consequently should not be rated as such, and that you should not be called upon to pay rates on them as houses. In order to sustain this contention you would have to show that the houses were not fit for human habitation. The only way I see you could expeditiously do this would be by applying to the justices to have the houses closed as unfit for human habitation, or agreeing to such an order being made at the suit of the sanitary authorities. Even then you would not be out of difficulties, as you would have to get the rating adjusted on this proviso. When all this is satisfactorily accomplished a considerable amount of money and time will have been expended. This brings us to the question, would it not be better for you to execute the repairs required by the sanitary authorities? In answering this question I may premise that the sanitary authorities *very* frequently request repairs, &c., to be executed which are entirely beyond their powers, and which are, moreover, quite unreasonable and possibly unnecessary. It appears in this case that the sanitary authorities have not stated what repairs they require. You should write to them requesting to be furnished with full particulars, and stating that you are willing to execute all proper and reasonable works. If in the face of this they refuse to state what they want, let them proceed. Attend at the hearing before the magistrate and state that you are and were quite willing to do what is necessary to the premises, but that the sanitary authorities will not inform you of their requirements. If you state your case properly I have no doubt the magistrate will rule in your favour. On the other hand, if the sanitary authorities furnish you with particulars of what they require to be done, you should communicate with a solicitor to advise you as to its legality. Unless the premises are in such a condition that they are absolutely not worth repairing, I think it will be better for you to comply with the sanitary authorities' requirements. Without seeing a copy of the agreement entered into between yourself and the urban council, I am not in a position to advise you as to its effect.

W. JOHNSON-ROBERTS.

Levelling with Theodolite.

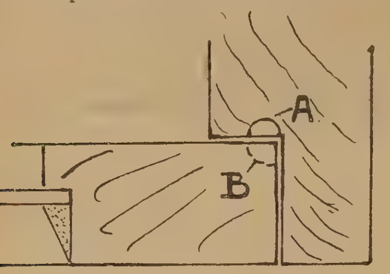
LOWESTOFT.—S. A. C. writes: "(1) Can I set a plain 6in. theodolite so that it can be used in exactly the same way as a dumpy level, reading the rise and fall on the staff, and can levelling be done as accurately? (2) Are iridium points with stadia reading used in plain theodolites; if not, could they be fitted? (3) Could a small survey of a farm be made as well with a dumpy level and compass fitted under it as with a theodolite? (4) Which is the most practical book on surveying and levelling with a description of the instruments used?"

(1) By clamping the vertical arc at zero, a theodolite may be used in precisely the same way as a dumpy level. (2) Iridium points are supplied with most modern instruments, but if they are lacking they can always be fitted. My own instrument has been fitted for stadia reading in this way, but the lines are permanently drawn on a glass diaphragm instead of iridium points. (3) A compass is far too inaccurate to be in the least relied upon. Besides the difficulty of reading it accurately, the needle is continually being affected by external influences such as iron railings, &c. (4) I should like to recommend my own book, "Surveying and Surveying Instruments" (Whittaker & Co.),

but fear the first edition is out of print, while the second will not be ready for a few weeks yet. G. A. T. M.

Making Casements Water-tight.

HANDSWORTH.—HANDS writes: "Some casement windows let in driving rain very badly. I presume this would not have happened had a groove been put in the frame at A on sketch. On account of expense I do not want to take out the frames. Would it remedy matters if the inner edge of the casements were cut away as marked at B?"



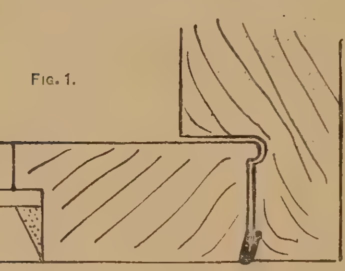


FIG. 1.

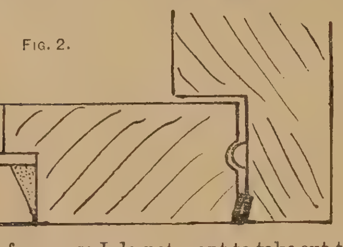

FIG. 2.

A hollow at B would be useless. The correct form of joint is shown in Fig 1. As you do not wish to take out the frames and alter them, we advise you to put a bead on the frame and make a corresponding groove in the casement as in Fig. 2, which should be fairly water-tight.

Building Trade Catalogues.

MOBBERLEY.—FOREMAN BRICKY writes: "Why are advertisers who are manufacturers of goods used in the building trade so chary in sending their catalogues to anyone who has not a printed trade card or memorandum form?"

The catalogues of many firms who supply the building trade are costly to produce, and it is only to be expected that they do not wish to waste them on persons who are not likely to become customers; hence the reticence you refer to, though for our own part we have always found that the firms are very generous in sending out copies of their catalogues to all and sundry. It should also be remembered that, besides the cost of the catalogue itself, there is the postage on it; and business houses are not philanthropic institutions.

Books on Sewage Matters.

LONDON.—E. E. B. writes: "Kindly recommend a work dealing with the different methods of sewage-disposal now in use, and their respective merits; the law relating to the responsibilities of the various local authorities; and also the limits of their power: for instance, I am told that they have no legal power to compel the owner to put in surface-water drains under roadways. Also a book giving practical formulæ or tables for determining the size of the proposed sewers for new roads, correct distances apart for storm gulleys, and road drainage generally."

The most recent and comprehensive work dealing with the various subjects mentioned is "Specification No. 5" (published at these offices, price 5s.). The following works, treating of the different phases of sewage-disposal, &c., are also recommended:—Santo Crimp's "Sewage-disposal Works" (Griffin & Co., 30s.), illustrating methods of land purification of sewage; Rideal's "Sewage and the Bacterial Purification of Sewage" (Ingram, 14s.) for biological systems of purification; and Poore's "Dwelling-House" (Longmans, Green & Co., 6s. 6d.) for details of the dry-earth system for country houses, &c. The legal duties and responsibilities of local authorities and the statutory limitation of their powers are described in "Knight's Annotated Bye-laws," (Knight & Co., 12s. 6d.) and in Stevenson & Murphy's third volume of "Hygiene and Public Health," which deals with sanitary law (Churchill, 28s.). Another useful little brochure is Ravenhill's "Elements of Sanitary Law" (Sanitary Publishing Co., 6d. nett). Practical formulæ for the determination of the size of sewers, together with details of sewer construction, road drainage, &c., will be found in Savage's "Sewerage and Sewage-disposal of a Small Town" (Biggs & Co., 5s.); also in Moore's "Sanitary Engineering" (Batsford, 30s.). With regard to the provision of separate surface-water drains to new buildings, it was decided last year in the Court of Appeal (*Matthews* v. *Strachan*) that in considering what is "necessary for the effectual drainage" of a new house under section 25 of the Public Health Act of 1875 the local authority cannot take into consideration what is desirable for the sewage-disposal of the district generally, so that the local authority cannot therefore insist upon separate drains for sewage and surface-water. We are, however, unable to find any authoritative decision that it is contrary to the provisions of the Public Health Act to require separate surface-water drains or sewers to new streets if considered necessary.

T. E. C.

Varnishing on Outside Doors.

LEICESTER.—R. G. writes: "(1) The outside woodwork of my house was painted and finished with a coat of varnish, in the summer. After a driving rain, it has a milky appearance which disappears in time. What it the cause of this? (2) Kindly name a good book on measuring timber, deals and hardwood (logs squared and round and uneven), with tables, and the customs adopted in the timber trade."

(1) A coat of varnish although good, often gets a "bloom" upon it from bad application. Damp wood on which it is applied is one of the most frequent causes, and it is also caused by damp before the varnish is dry. The peculiar effect rain has in the case you instance, we cannot explain, assuming your account to be correct, but we should think the varnish was not good. (2) W. Richardson's "Practical Timber Merchant," price 3s. 2d. post free, from Mr. B. T. Batsford, 94 High Holborn, W.C.

Thickness of Plastering.

TODMORDEN.—STUDENT writes: "(1) What should be the thickness of three coats of plaster on lath-and-half laths? (2) What quantity of sand should be used with 100 tons of stone lime for three-coat plasterwork on laths?"

Lath-and-half laths are about $\frac{1}{4}$in. thick. The first coat should not be less than $\frac{3}{8}$in. and not more than $\frac{5}{8}$in.; the most suitable thickness is $\frac{1}{2}$in. The second or floating coat should be not more than $\frac{5}{8}$in. or less than $\frac{3}{8}$in. thick. The setting coat should not exceed $\frac{3}{16}$in. or be less than $\frac{1}{16}$in; $\frac{1}{8}$in. is best. The three coats should not be less than $\frac{3}{4}$in., and with the laths should occupy 1in. (2) 100 tons of stone lime should be used to every 400yds. of sand and 600 bushels of hair (this latter must not be omitted).

Compensation from a Trade-Union.

R. G. writes: "A member of a trade society resigns, and thus becoming a 'non-unionist' the union men refuse to work with him, so that he must either leave or be discharged. Can he claim compensation from the Society for loss sustained whilst out of work?"

We do not know of any similar case having been decided at law; but if there were no remedy it would be contrary to every principle of right. Such an action by a trade-union is practically a case of boycott, and the offence is criminal. It has been decided in the case of *Taff Vale Railway Co.* v. *Amalgamated Society of Railway Servants* that a labour union can sue and be sued in respect of wrongs committed by or against it. If, therefore, it could be proved that a workman had suffered loss by the action of a trade union, compensation could undoubtedly be obtained.

Pope's Villa and Walpole's Villa.

SOUTHPORT.—F. H. C. writes: "I am much obliged to Mr. Burgess for his information about Horace Walpole's villa. A short time ago I rode on the top of a 'bus from Richmond to Hampton Court. Pope's villa, at Twickenham, I understand to be a comparatively modern house erected on the site of the house in which Pope lodged. Is this so? Further on we passed a plaster castellated building which it struck me might very well answer to Horace Walpole's villa. This was at Strawberry Hill. I had a distinct recollection, however, of having read that Walpole's villa had ceased to exist. Is this so, or is this house really Walpole's building?"

The "castellated" building which "F. H. C." passed on his ride from Richmond to Hampton Court is the house which Horace Walpole built and lived in. He is also correct about Pope's villa, which is on the same route. The house which Pope bought (with money obtained from the sales of the first portions of his translation of the Iliad) consisted of a small body with a small hall, paved with stone, and two small parlours on each side; the upper storey being disposed on the same plan. This house was contained by the river on one side, and the road—Cross Deep—on the other. He also purchased an extensive garden on the opposite side of the road, and he connected the house with the garden by means of a tunnel under the road. This tunnel was embellished with many devices to make it appear a grotto. A plan of the grotto and gardens, and a catalogue of the ores, spars and gems which enriched it, with the names of those persons who had been benefactors to it, was published in a brochure by J. Serle, Pope's gardener, in 1745, a year after Pope's death. The cost of constructing the grotto and laying out the gardens is given as £6,000. Dr. Johnson remarked: "A grotto is not often the wish or pleasure of an Englishman, who has more frequent need to solicit than exclude the sun; but Pope's excavation was requisite as an entrance to his garden; and as some men try to be proud of their defects, he extracted an ornament from inconvenience, and vanity produced a grotto where necessity enforced a passage." After being in the possession of several worthy people, the house was bought in 1807 by Baroness Howe, who preserved the grotto, but entirely demolished the house, and erected at a little distance a commodious family residence; this was at a later period divided into two houses. The present house, "neither like Pope's house nor any other," was built by Mr. Thomas Young (not, however, on the site of Pope's). It has been described as follows: "It is a combination of an Elizabethan half-timber house and a Stuart Renaissance, with additions of Dutch, Swiss, Italian and Chinese features, probably designed when its architect was fresh from a diligent study of the paintings in Lord Kingsborough's work on Mexican antiquities." This house is at present occupied by Mr. H. Labouchere.

As regards Walpole's villa, Walpole purchased the place in 1747, when it was but a "little plaything house." The "Castle," as he called it, was formed by alterations and additions to the old small house. The library and refectory were built in 1753; the gallery, round tower, great cloister and cabinet in 1760; the great north bedchamber in 1770; and the Beauclerk tower with hexagon closet in 1776. Lord Macaulay says: "Every apartment is a museum, every piece of furniture is a curiosity; there is something strange in the form of the shovel, there is a long story belonging to the bell-rope." Walpole's aim in designing it was the revival of Gothic domestic architecture. It is constructed in a kind of concrete. Its general effect would be more pleasing at a distance. Although he persevered with his intention, Walpole does not seem to have been altogether satisfied with the result, for he makes many apologies for it, the best of which was that it is "a fantastic fabric." A full account of the buildings, with plans, elevations, details and interior perspectives, as well as a catalogue of the numerous and valuable art treasures it contained during his lifetime, may be read in the second volume of his works.

ALFRED BURGESS.

Bricks and Mortar.

APHORISM FOR THE WEEK.

The majority of men prefer the worst architect and the most slap-dash way of dealing with the work, and would give anything to be rid of the restraint which a conscientious architect imposes upon their wishes.—SIR GILBERT SCOTT.

Our Plates. THE Roehampton Club for Working Girls, Cornwall Road, S.E., is situated in a very poor and thickly-populated part of Lambeth. It was built and opened for its work in 1900, and the accommodation provided comprises a large reading- and games-room on the ground floor and lavatories in the rear. On the first floor are two class-rooms and a small kitchen or cooking room for the use of the girls, and on the second floor a kitchen and two bedrooms are provided for the caretaker. The external walling is built in stock brickwork, with red-brick relieving arches over the windows, &c. The roof is covered with grey slates. All the external woodwork is painted white. The whole of the work was well executed by Messrs. Garratt & Son, builders, of Old Town, Clapham, S.W., from the designs of Mr. W. G. Horseman, architect, of 67, St. George's Road, S.W., and the cost, exclusive of the site, was just under £1,000. The site being very much out of square, was not easy to deal with, but the rooms as finished do not show this internally to any extent. The funds available precluded any elaboration.

The Alterations at Windsor Castle. MESSRS. WARING are carrying out the alterations at Windsor, which are now sufficiently near completion to allow a description of them to be given. In the private royal apartments, where the importance of the work centres, a brilliant effect has been obtained by employing large surfaces of cream-white as a background for the works of art. In the king's bedroom the colour predominating is an Irish green. The King's sitting-room is the one in which the late Prince Consort passed his last hours, and the whole of the interesting features which identify the room with Prince Albert have been preserved. The ceiling has been slightly reduced in height; an eighteenth-century raised moulding in flowers and fruits of a simple form occupies the centre, with a console cornice. The whole is left a perfectly plain white. Below is a deep frieze or band of soft-coloured green. The room has a high wooden dado, with bevelled panels and pilasters, forming an excellent background for the favourite family portraits which adorn the room. Her Majesty's bedroom is panelled in a soft rose silk, and the windows are hung with a pure white soft satin, which hangs in ample folds and gives the necessary cool effect. The whole of the furniture is of the Empire period in design. The bathroom adjoining is panelled with marble on one side and Sheraton woodwork on the other. The marble employed both in the King's and Queen's bathrooms is of Greek origin, from the quarries which have been reopened within the last year after having been lost sight of for over 1,000 years. For the royal boudoir old Louis XVI. furniture has been rummaged out from another part of the Castle and covered in a soft-coloured Beauvais tapestry, and the carpet manufactured in France at the State factories is remarkably tender in colour, taking up the mother-of-pearl tints of old rose, green, blue, cream, &c. The broad old-fashioned gilt moulding round the panels has been retained and the centre filled in with beautiful silks. The old satin-wood doors have been replaced by Spanish mahogany with bronze ornaments. In addition to the decorations considerable improvements, amounting to reconstruction, have been made in the sanitary arrangements of the southern part of Windsor Castle by the officials of his Majesty's Office of Works, under the advice and supervision of Professor Corfield, their consulting sanitary adviser. The whole of the drains under the south towers, from Edward III.'s Tower to the Victoria Tower inclusive, have been done away with, so that there is now no drain under the buildings on that side of the Castle, and new water-tight iron drains have been laid outside the buildings. Similar improvements will gradually be carried out throughout the rest of the Castle.

Builders' Notes.

"The Quarry" Collection of Building Stones was inspected on December 14th last by the Battersea Polytechnic Architectural Society, when Mr. J. V. Elsden, B.Sc. (London), F.G.S., delivered a lecture on them. This lecture has now been reprinted in pamphlet form by "The Colliery Guardian" Co., Ltd., 49, Essex St., Strand, W.C.

The Aberdeen Master-Slaters' Association held its first annual meeting last week, when the following office-bearers were appointed:—President, Mr. James Wright, 5, Belgrave Terrace; vice-president, Mr. James Wilson, 79, Spring Garden; treasurer, Mr. Robert Stuart, jun., 35, Holland Street; committee, Messrs. Merson, Kincaid, Farquhar and Martin; secretary, Mr. P. W. L. Clark, solicitor, 259, Union Street. Auditors, Messrs. A. Kincaid and Macdonald.

Fire Tests with Warehouse Floors.—The British Fire Prevention Committee have arranged for a very important test to take place to-day with a large warehouse floor constructed entirely of Karri and Jarrah wood, the floor being constructed on the same principle as recently adapted for the big warehouse in the new Free Port at Hamburg. There will also be tests with Karri and Jarrah doors for comparison with the fire-resistance of oak and teak doors.

Partnership Dissolved. — The partnership between Messrs. Samuel James Chambers and George Chambers, carrying on business as builders and contractors at Dorset Road and Weymouth Avenue, South Ealing, and at the Grove, Ealing, under the style or firm of Chambers Brothers, has been dissolved by mutual consent as and from November 5th last. All debts due to and owing by the late firm will be received and paid by Mr. Samuel James Chambers.

The Executive of the British Fire Prevention Committee announce that the silver medal which they offered for the best essay on fire-resisting materials exhibited at the International Fire Exhibition of 1901, at Berlin, has been awarded to Lieutenant Elener, of Berlin, the assessors being Chief Officer Giersberg, of Berlin, and Mr. Edwin O. Sachs, chairman of the Committee. The essay will be published in the official Government report of the Exhibition in the German language, and also in the Committee's publications in an English translation.

City and Guilds of London Institute: Department of Technology.—With the view of allowing candidates for the honours grade examination in painters' and decorators' work a longer period in which to execute the practical tests for that examination, the Institute has decided, as notified in the report on the work of the Department, to issue particulars of such tests to all centres at which classes in the subject are held, by Saturday, February 8th, instead of by March 1st, as stated in the programme. The candidates' prepared work must be forwarded to the Institute on or before Saturday, March 22nd. External candidates who wish to present themselves for the examination should apply for particulars to the Superintendent, Department of Technology, City and Guilds of London Institute, Exhibition Road, London, S.W.

The Mason Trade in South Africa.—A correspondent, who has been about thirty years at Cape Town, writes: "When the war is finished there will be hundreds of masons among the refugees and colonials already in the country who will only be too glad to avail themselves of the opportunity to work on the projected railways. As regards hewing, there is nothing in the whole country at present; there is any amount of material, and all kinds of the best stone; but it requires the railways extended throughout the country, and that will take several years; then stone and slate will be easily and cheaply conveyed to growing townships. As regards masonwork on the railways, it is far different from the style of work at home; there is no such thing as skewed arches, or neatly scabled ring-heads; it is mostly all from the spauling hammer (Cornish style), and then the stone is nearly all granite or bastard stone that they use on railway works. Still I believe there is a great future for the building trade out there, but the country will have to get over the effects of the long war before the mason trade will be brisk (I mean for hewers)."

The Aberdeen Master-Painters' Association held its annual meeting last week, when office-bearers were elected as follows:—President, Mr. Alexander Latto; vice-president, Mr. William Philip; secretary and treasurer, Mr. J. B. Davidson, of Reid & Davidson, advocates; committee, Messrs. Henry Donald, John Mason, Edward Copland, Adam Buchan, C. R. Fraser and J. W. Forrest.

London County Council.—At last week's meeting of the Council Mr. Davies, chairman of the Improvements Committee, informed Mr. Emden that the question of widening Piccadilly from the Circus westward was under the consideration of his committee, and it entirely depended upon the sympathy that would be shown by freeholders and leaseholders affected as to whether a report would be presented or not.—A resolution was passed referring to the Highways Committee to consider and report on the best means for the Council to obtain such statutory powers as to insist on inadequate notice being given before opening roads or streets, and also for the Council to superintend and expedite such work.—A motion was adopted referring to the Highways Committee the question of some "over and under" provisions, by means of bridges or subways, to cope with cross-traffic in streets.

Surveying and Sanitary Notes.

Competition for Laying-out Estate.—Plans recently submitted in open competition by Mr. Ernest E. Ellis, architect, Exmouth, for laying-out a building estate near London, have been judged the best. The estate is a very large one, and contains about 1,500 acres.

"Insanitary Angles."—Mr. Mark H. Judge, A.R.I.B.A., has addressed a letter to the mayor, aldermen and councillors of Hampstead (in pamphlet form) in reference to the drains of 70, Canfield Gardens, Hampstead, objected to by the borough sanitary inspector (as reported in our issue for December 11th, 1901).

Epping Forest Improvements.—In 1897 suggestions were made to the Corporation of London by the local authorities that a large ornamental pond should be constructed in the Forest between Whipps Cross Road, Leyton, and the Snaresbrook Road, on a swampy and uneven portion of the Forest, known as the Hollow Pond, and the Corporation provided £650 towards the cost. The work was immediately put in hand, and completed at an expense of £1,228. The Corporation now consider that a great improvement would be effected if the area of the pond were extended by the addition of about three acres at a cost of about £1,800.

A Criticism of the Designs for Birmingham University.—In the course of his presidential address to the Midland Arts Club last week Councillor J. W. Tonks contended that the true art of architecture consisted in the right and balanced application of right lines, sloping lines and curves. In modern buildings they saw nothing but a series of vertical lines, and he held it to be barbarous and contrary to the best traditions. In this connection he severely criticised the designs for the proposed Birmingham University buildings (by Messrs. Aston Webb and E. Ingress Bell). He described them as a series of blocks or square towers at intervals like gate-legged tables set on end, with a flattened dish-cover in the centre of each to serve as a dome. As one stood opposite them he would see nothing but a monotony of barbarous vertical lines, and the flattened domes would only seem to weigh like a nightmare on the soul. The style was called Spanish, but he thought it was Saracenic. The Trocadero in Paris was built on somewhat similar lines, but there the towers were not at the corners. The two mighty towers approaching the centre gave picturesqueness to the whole, and the building was thrown into a noble curve, but it was a failure, and so would the University be if built on the proposed plans.

RECENT DATA CONCERNING CONCRETE BEAMS AND CONCRETE FLOORS.*

BY JAMES BRUCE.

CONCRETE, whether used for foundations, walls or floors, is of great and increasing interest to us as architects. As an Association it has come under our consideration many times, both in lectures and in visits to works in progress, and in the future it will be still more forcibly brought before us. Those who live into the middle of this century will see its use still more widely extended, and it becomes us to prepare for this increasing application by studying its resources and experimenting upon its properties. We are, as a body, so conservative and reluctant to adopt either new methods or new materials that any attempt to extend our knowledge in either direction will rightly be subjected to rigid scrutiny. Not that concrete is in itself a new material—for is not the dome of the Pantheon partly constructed of concrete?—but its use for beams and floors is comparatively recent. Entire buildings, including domes and bridges, are now constructed in armoured concrete. We have in this city a large warehouse at present in course of erection on the Hennebique system of ferro-concrete, to which this Association paid a recent visit. Engineers, at any rate, are not afraid of it; and that leads me to say that if we do not make ourselves well acquainted with concrete as a building material, the designing of such structures will naturally pass to the engineer, and he will not be slow to take advantage of it.

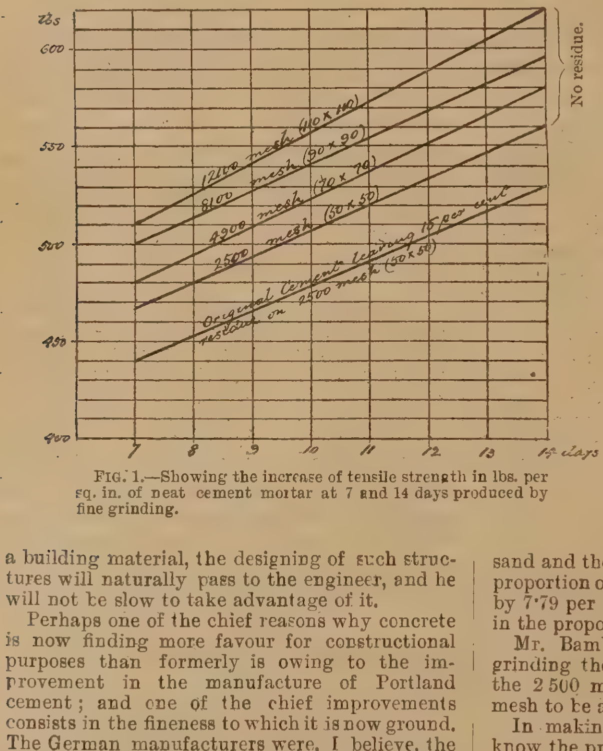

FIG. 1.—Showing the increase of tensile strength in lbs. per sq. in. of neat cement mortar at 7 and 14 days produced by fine grinding.

Perhaps one of the chief reasons why concrete is now finding more favour for constructional purposes than formerly is owing to the improvement in the manufacture of Portland cement; and one of the chief improvements consists in the fineness to which it is now ground. The German manufacturers were, I believe, the first to produce that extreme fineness of grinding which is now considered to be the best test of Portland cement. In Germany to-day cement can be obtained which leaves less than 10 per cent. residue on a sieve of 32,200 meshes to the square inch.

Of two cements of the same age and from the same maker the finer-ground variety will invariably be found to be the stronger. This is shown in Fig. 1, where the original cement as it came from the bag was tested and found to leave a residue of 15 per cent. on 2,500 mesh (50 by 50). It was tested for tensile strain at seven and fourteen days, after being kept six and thirteen days in water respectively, and the strain was applied at the rate of 100lbs. every fifteen seconds. The results given are the mean of six briquettes in each case. A quantity of the same cement was then taken and ground over again so that it now all passed the 2,500 mesh. It was then tested, and showed an increase of strength. The same cement was ground still finer so that it all passed the 4,900 mesh and tested, and so on to the 8,100 mesh and the 12,100 mesh, each test showing an increased strength. (This and the following diagrams are taken from tables given by Mr. H. K. C. Bamber in a paper read before the Incorporated Association of Municipal and County Engineers at the annual general meeting held at West Bromwich on July 14th, 1893.)

But the increase in the strength of finely-ground cement is better seen in Fig. 2, which gives the results of tests made with briquettes mixed in the proportion of 3 of standard sand (all to pass a 20 by 20 mesh and be retained by a 30 by 30 mesh) to 1 of cement. After each experiment the cement was ground to a finer quality, as in Fig 1, and then subjected to the next higher test. As before, the original cement left 15 per cent. on the 2,500 mesh, and when mixed in the proportion of 3 of sand to 1 of cement broke with 154lbs. per sq. in. at twenty-eight days (twenty-seven in water). The cement was ultimately ground to all pass a 12,100 mesh and then tested. It was found that it broke with a tensile strain of 294lbs. per sq. in., which is nearly double (90·9 per cent.) the original strength (154lbs.).

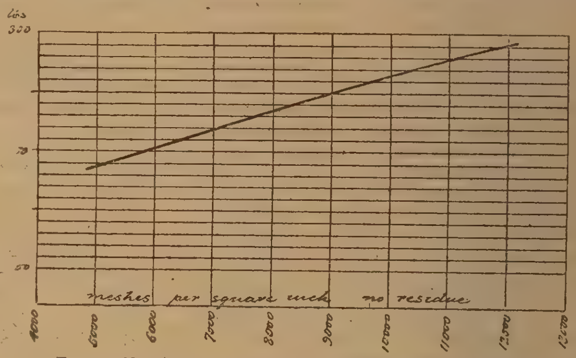

FIG. 2.—Showing the increase of tensile strength in lbs. per sq. in. at 28 days of cement mortar (1 cement and 3 sand) produced by fine grinding.

Mr. Bamber has also made another series of tests in which he gradually reduced the proportion of cement to sand as the cement was ground finer until he at last reached the proportion of 3 of sand to ½ of cement, which gave a tensile strain of 166lbs., the cement having all passed the 12,100 mesh. The original cement, as before, gave 15 per cent. residue on the 2,500 mesh and broke with 154lbs., and was mixed in the proportion of 3 of sand to 1 of cement; so it is evident that by using the same sand and the former fine-ground cement in the proportion of 3 to ½ a stronger mortar is obtained by 7·79 per cent. than by using mortar mixed in the proportion of 3 to 1 of ordinary cement.

Mr. Bamber states that the extra cost of grinding the ordinary cement (15 per cent. on the 2 500 mesh) until it all passes the 12,100 mesh to be about 6s. per ton.

In making concrete it is very important to know the proportions of voids in the aggregate. This can easily be found by experiment. The best concrete is made by selecting the most suitable aggregate and filling all the voids with a matrix as strong as the aggregate itself. Each separate piece of aggregate must be surrounded by the matrix to form a mortar joint at least ⅛in. thick. In this way, after being gently punned, solid concrete will be formed. To find the correct amount of mortar to fill all the voids and surround each stone or pebble with such a joint, it is necessary to add 10 per cent. of the bulk of the aggregate to the voids already found by experiment: because in measuring the voids in any given aggregate the separate pieces are all touching, and the thing to aim at in making concrete is not to have any of the separate pieces of aggregate touching but to form a mortar joint around each piece; hence the necessity of adding 10 per cent.

Many experiments have been made to find the proportions of voids in different kinds of aggregate, and I would here like to direct your attention to those made by Mr. J. Watt Sandeman, M.I.C.E., of Newcastle, who has given a great deal of study to this subject. He found that the voids in broken stone of various sizes ranged from 34 per cent. to 50 9 per cent. of their bulk, and in gravel consisting of small pebbles up to those which would pass a 2½in. ring the percentage was 33·6. I recently made two experiments myself to find out the amount of voids in brick aggregate broken to pass a 3in. ring, and found that one result gave 51 and the other 52 per cent.

When the aggregate is broken to various sizes, large and small, the proportion of voids is less than when broken to a uniform size, because the little pieces tend to fill up the spaces between the larger ones.

That concrete is often made with an insufficiency of mortar to fill all the voids is a fact which has come under my own observation. When it is used for foundations, such cavities or air-spaces (if they are small) do not perhaps detract to any appreciable extent from its strength, because the concrete is almost entirely in compression; but when the same material is used for beams or flooring slabs any cavities or air-spaces occurring must reduce its transverse strength very considerably, and if situated in the lower half of the beam or slab they are simply fatal to its strength.

To fill the voids in the aggregate, the mortar must be mixed with the proper amount of water. If less than the proper amount is used the mortar occupies more bulk than it would otherwise do, and in setting it leaves cavities. That such cavities do sometimes exist in slabs used for flagging purposes the following case mentioned by Mr. Bamber will show. He was consulted as to the reason why certain concrete flags after rain always remained wet and seemed to absorb water very easily, while their neighbours made from the same cement soon became dry. By experiment he found that enough concrete composed of 1 cement, 2 sand and 4 shingle could be made to fill a box 18in. cube by using 40lbs. of water. Again, by using only 15lbs. of water, the other proportions being the same, he could only get seven-eighths of the bulk of the resulting concrete into the same box. Hence, he concluded that of flags of the same size made in the above proportions the one mixed with the least water contained cavities amounting to one-third of its bulk, and he thought the explanation of the wet and dry flags was that the rain soaked those having air-spaces which filled with moisture and only evaporated very slowly. It appears paradoxical to say that the flags remained wet because they were made too dry, but such appears to be the case.

Coming now to some actual experimental data concerning concrete slabs, it is proposed to compare those tested at London in March, 1896, by Messrs. Fowler & Baker with those at Gallowgate in September, 1899. The latter were carried out jointly by a committee of this Association together with representatives from the local master-builders' association and the Council of the Building Trades' Exchange. The age of the slabs at the time of testing was in both cases nearly the same, the London ones being sixty-three days old and the Gallowgate ones sixty-one; while the cement used in the latter case was rather finer ground and weighed less than that used in the London slabs.

To begin with the Gallowgate slabs. These were made without expanded metal in the proportion of 1 cement, 1 sand and 4 clean-washed gravel, to pass a 2in. gauge. They were of different spans, but were all 8in. thick and 4ft. wide. The gravel must have contained voids to the amount of one-third of its volume.

---

* A paper read before the Northern Architectural Association at Newcastle on January 15th, 1902.

One volume of cement and 1 of sand would, on being made into mortar, only occupy ·76 per cent. of its former volume—that is, $2 \times \frac{76}{100} = 1{\cdot}52$ volumes of finished mortar. (This data is taken from the experiments by Mr. Sandeman before referred to.)

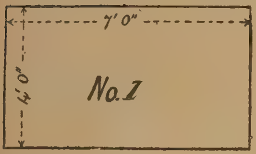
To make solid concrete, the mortar should fill all the voids plus 10 per cent. of the volume of the aggregate. The amount of gravel whose voids the 1·52 volumes of mortar will fill in this way can be found thus:—

Let A represent the volume of gravel required. The voids in A are $\frac{A}{3}$, to which must be added 10 per cent. of A, or $\frac{A}{10}$. These two expressions must equal the amount of mortar as above.

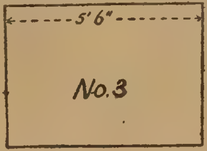
$$\therefore \frac{A}{3} + \frac{A}{10} = 1{\cdot}52.$$

$$\frac{13A}{30} = 1{\cdot}52.$$

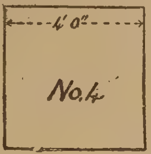
$$A = 3{\cdot}5 \text{ volumes of gravel.}$$



Superimposed weight	-	9
Weight of slab	-	23
Total breaking weight	-	32 cwts.



Superimposed weight	-	22·66
Weight of slab	-	18·07
Total breaking weight	-	40·73 cwts.



Superimposed weight	-	124·678
Weight of slab	-	13·142
Total breaking weight		137·82 cwts.

Therefore the proportions of 1 cement, 1 sand and 4 gravel will not make solid concrete. The gravel in certain places will be quite bare of mortar, and when subjected to transverse strain will be weak. To make solid concrete we may either reduce the amount of gravel to $3\frac{1}{2}$ parts or increase the mortar to 2·28 parts. The proportions will then be 1 cement, 1 sand and $3\frac{1}{2}$ gravel, or $1\frac{1}{7}$ cement, $1\frac{1}{7}$ sand and 4 gravel; the former proportion is preferable.

Coming now to the actual tests at Gallowgate. Three slabs of concrete in the proportion of 1 cement, 1 sand and 4 gravel, sixty-one days old, were loaded with an equally distributed weight until they broke. They were each 4ft. wide and 8in. thick, and of the above clear spans.

As the slabs had to carry their own weight in addition to that imposed on them, it is necessary to find the weight of each slab and add it to the superimposed weight. The total thus obtained is the breaking weight of each. It would have simplified matters if a few of the slabs had been weighed before testing, and an average weight per cub. ft. thus obtained. As this was not done, the weight of the slabs will have to be found from the given data thus:—

"The stability of a loaded beam is founded on the equality that must always exist between the resultants of all the external forces tending to cause its rupture and the sum of the molecular forces which resist the same." Practically these may be resolved into $M = R$, where M denotes the external forces and R the internal molecular forces; or, in other words, M stands for the bending moment and R for the moment of resistance. The bending moment for a beam with a distributed load supported at the ends is $\frac{WL}{8}$ where W is the weight and L the span. The moment of resistance for a rectangular beam is $\frac{CBD^2}{6}$, where C is a constant depending on the nature of the material, B the breadth and D the depth.

As stated, the bending moment is equal to the moment of resistance,

$$\therefore \frac{WL}{8} = \frac{CBD^2}{6}.$$

To apply this expression to the two slabs No. 1 and No. 3, let x denote the weight of No. 1 in cwts. and y of No. 3; L, the length of No. 1, is 7ft. and $5\frac{1}{2}$ft. for No. 3. The superimposed weights are 9 cwts. and 22·66 cwts. respectively. Substituting these values, the foregoing expression now becomes

$$\text{For No. 1 slab, } \frac{7(9 + x)}{8} = \frac{CBD^2}{6}.$$

$$\text{For No. 3 slab, } \frac{5{\cdot}5(22{\cdot}66 + y)}{8} = \frac{CBD^2}{6}.$$

$$\therefore 7(9 + x) = 5{\cdot}5(22{\cdot}66 + y).$$

$$63 + 7x = 124{\cdot}63 + 5{\cdot}5y$$

$$7x = 61{\cdot}63 + 5{\cdot}5y \quad \ldots \ldots (1).$$

We also know that the weight of No. 1 slab is to the weight of No. 3 slab as the span of No. 1 is to the span of No. 3. Therefore, we have this proportion:—

$$\frac{x}{y} = \frac{7}{5{\cdot}5}$$

and

$$y = \frac{5{\cdot}5x}{7}.$$

Substituting this value of y in (1), we get

$$7x = 61{\cdot}63 + \frac{30{\cdot}25x}{7}.$$

$$49x = 431{\cdot}41 + 30{\cdot}25x,$$

$$18{\cdot}75x = 431{\cdot}41.$$

$x = 23$ cwts. = the weight of No. 1 slab, from which we find the weight of a cub. ft. of the concrete to be 138lbs. The weight of all the other slabs can now be found.

To compare the transverse strength of the various slabs it is only necessary to find the value of C in the original expression

$$\frac{WL}{8} = \frac{CBD^2}{6}.$$

Taking slab No. 1 and substituting the proper values in the above, we get

$$\frac{32 \times 84}{8} = \frac{C \times 48 \times 8 \times 8}{6}$$

$$C = \frac{21}{32} = 0{\cdot}656 \text{cwts. per sq. in. for No. 1 slab.}$$

$$C = 0{\cdot}656 \text{ cwts. per sq. in. for No. 3 slab.}$$

(L, B, and D are taken in inches and W in cwts.)

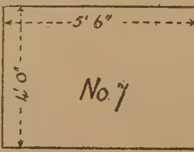
The weight of No. 4 slab is 13·142 cwts., and the superimposed weight is 124·678 cwts.; therefore, the total weight which broke the slab is 137·82 cwts., and the value of C is found as above thus:—

$$\frac{137{\cdot}82 \times 48}{8} = \frac{C \times 48 \times 8 \times 8}{6}$$

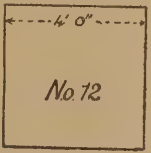
$$\frac{413{\cdot}46}{256} = C$$

$$1{\cdot}615 \text{ cwts. per sq. in.} = C \text{ for No. 4 slab.}$$

The next two slabs, No. 7 and No. 12, were both composed of 1 cement, 1 sand and 2 gravel, to pass an inch gauge. They were each $4\frac{1}{2}$in. thick and 4ft. wide, and of the following clear spans:—



Superimposed weight	-	17·47
Weight of slab		10·16
Total breaking weight	-	27·63 cwts.



Superimposed weight	-	10·83
Weight of slab		7·39
Total breaking weight	-	18·22 cwts.

$$\text{For No. 7 slab, } \frac{27{\cdot}63 \times 66}{8} = \frac{C \times 48 \times 4\frac{1}{2} \times 4\frac{1}{2}}{6}$$

$$C = 1{\cdot}407 \text{ cwts. per sq. in. for No. 7 slab;}$$

$$\text{and for No. 12 slab, } \frac{18{\cdot}22 \times 48}{8} = \frac{C \times 48 \times 4\frac{1}{2} \times 4\frac{1}{2}}{6}$$

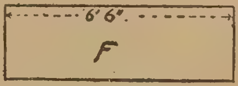
$$C = 0{\cdot}675 \text{ cwts. per sq. in. for No. 12 slab.}$$

No. 12, as the result shows, is abnormally weak, and should be discarded. If we compare it with No. 7, which is of the same proportions and broke with 27·63 cwts., we find that No. 12 only carries about one-half what we should expect.

As this completes all I have to say about the Gallowgate slabs, it will be convenient here to make a few remarks about the method of loading them. In using pigs of iron for the weight there is a slight tendency for them to form an arch, and thus the total weight of the pigs would not be the actual distributed load. A better way, in my opinion, would have been to have used bricks laid without any bond, the joints all being straight and perpendicular. There could not be any possibility of an arch being formed if that method had been used.

Turning now to the experiments made in London in 1896 by Messrs. Fowler & Baker, we find that the slabs were composed of 1 cement, 1 sand and 2 of Thames ballast, and were tested at the age of sixty-three days. They were each 2ft. wide and 3in. thick and of the following clear spans:—

Superimposed weight	-	18
Weight of slab		2·156
Total breaking weight	-	20·156 cwts.



Superimposed weight	-	6
Weight of slab	-	4
Total breaking weight	-	10 cwts.

The total breaking weights were 20·156 cwts. for E and 10 cwts. for F. The weights of the slabs have been taken at 138lbs. per cub. ft., as before.

Using the same formula as for the Gallowgate slabs, and substituting the proper values of the symbols, we have for E—

$$\frac{WL}{8} = \frac{CBD^2}{6}$$

$$\frac{20{\cdot}156 \times 42}{8} = \frac{C \times 24 \times 3 \times 3}{6}.$$

$$C = 2{\cdot}939 \text{ cwts. per sq. in. for E;}$$

and for F—

$$\frac{10 \times 78}{8} = \frac{C \times 24 \times 3 \times 3}{6}.$$

$$C = 2{\cdot}708 \text{ cwts. per sq. in. for F.}$$

These values for C agree pretty closely, and are about double those obtained for the Gallowgate slabs of similar proportions.

No experiments appear to have been recorded of concrete flooring slabs built in on all four sides, but a few have been published of those *supported* on four sides. Col. Seddon made some in 1874 at Chatham. In his experiments, which are given in the appendix to his volume on "Builders' Work," the slab nearly square is selected for comparison with those discussed above. It was composed of 1 part Portland cement to 4 crushed brick, to pass an inch mesh, and measured 14ft. 6in. by 13ft. 6in. between the supports. It was 6in. thick and weighed 121lbs. to the cub. ft., was well beaten down, and covered with water for seven days. After twenty-one days it was tested and broke with $10\frac{1}{2}$ tons distributed weight on the slab, or, including its own weight, 15·68 tons; that is 1·613 cwts. per sq. ft.

To compare this with the Gallowgate and London slabs, we apply this formula: for an oblong slab supported at its four edges the greatest bending moment is $\frac{WL^4B}{8(L^4+B^4)}$. This expression must be equated to the moment of resistance of the section along its length, which is $\frac{CLd^2}{6}$ $\therefore \frac{WL^4B}{8(L^4+B^4)} = \frac{CLd^2}{6}$. The distributed weight W is 315·7 cwts., including the weight of the floor; L, the length, and B, the breadth, both in feet; d, the depth in inches; C, as before.

$$\therefore C = \frac{3WL^3B}{4d^2(L^4 + B^4)}.$$

$$C = \frac{3 \times 315{\cdot}7 \times 14{\cdot}5^3 \times 13{\cdot}5}{4 \times 36(14{\cdot}5^4 + 13{\cdot}5^4)} = 3{\cdot}49 \text{ cwts. per sq. in.}$$

The strength of a slab uniformly loaded and fixed at the ends is at least $1\frac{1}{2}$ times that of one supported only, and the strength of a square slab fixed all round appears only to be $1\frac{1}{4}$ times that of one supported all round. But how much the strength of a rectangular slab is increased by fixing its edges all round over that of a similar one supported only at the four sides no definitite information has come under my notice.

More experiments are needed; and it is hoped that, with the increase of engineering laboratories at so many of the technical schools and colleges, we will not have to wait long for some such tests being undertaken. In the meantime, if we use the value of C derived from Col. Seddon's experiments of slabs supported on four sides, and apply a factor of safety of 5, we will be well within the limits of safety. As an example of this, let us take an actual warehouse floor which has stood for a number of years. Its dimensions are 21ft. by 12ft. 6in. by 13in. thick. Applying the formula for a rectangular slab supported at the four sides,

$$\frac{WL^4B}{8\,(L^4+B^4)}=\frac{CLd^2}{6}\ \therefore\ W=\frac{4Cd^2\,(L^4+B^4)}{3L^3B}$$

Substituting the value of C just obtained from Col. Seddon's slabs and the proper numerical values in the last formula, we get

$$W=\frac{4\times3{\cdot}49\times169\,(21^4+12{\cdot}5^4)}{3\times21^3\times12{\cdot}5}=1{,}487\text{ cwts.}$$

$W = 1{,}487$ cwts. total distributed breaking weight.

As the weight of the floor itself is about 306 cwts., it leaves 1,181 cwts. for the breaking weight on the floor; and with a factor of safety of 5 it will be seen that the floor will carry nearly 1 cwt. per ft. super. at the early date of three weeks. Col. Seddon's slab was only *supported* at its four edges, but this one was built in and the centering was allowed to stand for six weeks. At the end of that period it had, no doubt, an ample factor of safety.

Concrete is weak in resisting tensile stress; and the future of concrete flooring lies in its being reinforced with iron or steel, either by expanded metal at the under-surface or by means of steel rods, as in the Hennebique system.

Keystones.

A New Technical Institute at Dartford has been opened at a cost of £8,000.

A Monument to the Notable Surgeon Hollier, by Boucher, the sculptor, is about to be erected at Lyons.

The Jubilee Memorial of Queen Victoria at Buenos Ayres, provided by the loyalty of the British Colony, is a home for sailors, towards which £6,000 was raised as soon as the proposal was made, and for which the Argentine Parliament, by a unanimous vote, gave a valuable site on the new docks. This memorial building is now approaching completion.

A New Post-Office at Enfield is to be erected at the junction of Little Park and Church Street. The present offices are a part of the fine old Tudor building known as the Royal Palace. The south wing, with its tall brick chimneys, still remains, and within there are richly ornamented ceilings, oak-panelled walls, and a massive chimney-piece on Ionic and Corinthian columns, and here are seen the letters "E. R." (Edward VI.), with the arms of England and France quartered.

The Third Block of the New Admiralty Buildings has been commenced, and Messrs. Chessum & Son, of Bow, are now engaged upon the foundations. The architects of this third erection are Messrs. Leeming & Leeming, who have carried out the other two blocks. The new pile will, of course, correspond with the edifice overlooking St. James's Park, the characteristics of which were largely dominated by the original old Admiralty building to which it was an addition. The new structure on the Horse Guards' side of the quadrangle will probably constitute the most important frontage of the modern Admiralty. While, of course, the general style of it will be that of the two other portions, it will be somewhat more imposing and elaborate. A fourth addition is now in contemplation, and the probability is that before the Horse Guards' frontage has got far on its way a new building will be decided on to face Whitehall, and running down from the Park to the Paymaster's Office, thus effectually extinguishing Ripley's pillars and pediment which the screen on the street-frontage line was erected in some measure to mask.

A Monument to Victor Hugo, by M. Juste Becquet, is to be erected at Besançon, the natal town of the poet.

The Yarmouth Old Town Wall.—The Town Council have decided finally by 19 votes to 12 to demolish the Rampart Road Town Wall, notwithstanding three memorials from the Norwich Archæological Society, the secretary of the Society for the Protection of Ancient Buildings, and the inhabitants of the borough, urging its preservation.

The Ardrossan Co-operative Society has accepted the plans for new buildings sent in by Mr. Allan Gilfillan, Ardrossan. A two-storey block is to be erected with 300ft. frontage to Woodwynd and 37ft. frontage to Main Street, Ardrossan. The buildings will probably cost about £6,000. Architects were invited to send in competitive plans, and those sent in by Mr. Gilfillan were very favourably reported on by the assessor.

The First National Bank in Chicago is about to erect one of the largest office buildings in the United States at a cost of over £1,000,000. It will be sixteen storeys high, and will have a ground area double that of any other Chicago building. The Montauk building, a towering structure of twelve storeys, built a few years ago at a cost of £100,000, will be pulled down with other buildings to make way for the new Colossus.

A New Cold Storage Building in Newcastle is being erected for the Northern Counties Ice and Cold Storage Company, at the Quayside. The factory will contain about 250,000 cub. ft. for cold storage, and also an ice plant to make nearly 200 tons of clear ice per week. Messrs. Cackett & Burns Dick are the architects for the building, and the machinery and general arrangement of the factory is in the hands of Mr. Cott, of London, and Mr. Baxter, the Company's engineer.

A New Asylum at Winwick, near Warrington, was opened recently. Messrs. Neill & Sons, of Manchester, were the contractors, and the asylum has cost £253,000. It is built on the pavilion system, with a large administrative block in the centre and wards on each side connected by corridors. Accommodation is provided for 1,000 females and 1,000 males, and also 200 attendants. The cost, exclusive of furniture, totals up to £382,955, and the amount will be at least £400,000 when completed.

A Figure of Lord Roberts on a Reredos.—The new reredos which has been designed for the Church of St. Agnes, Bristol, as a memorial to the boys of Clifton College who have fallen in the war in South Africa, contains the figure of Lord Roberts. It is believed to be the first time a public man has been represented on such a piece of work, and it shows the Commander-in-Chief kneeling as if in the act of prayer. Behind him stand Dr. Browne, the Bishop of Bristol, and the figures of a nurse and a footballer.

New Board Schools at Cressing have been erected on the Braintree road, and are divided into three sections—infants, girls and boys; altogether there is accommodation for 200 children, and the school can be thrown all into one and made to hold a meeting of 300 people. Outside, the building is of red bricks and inside the walls, which are 14in. thick, have been coloured and have a dado of brown glazed brickwork. The builder was Mr. Frank Johnson, of Chelmsford; and the architects are Messrs. Clare & Ross, of Chelmsford. The contract price for the school, with extras, was £2,105, and with the other connected expenses the total cost will be £2,500.

The Withington Cemetery Buildings Competition.—The Withington Council have adopted the plans of Mr. Ernest Woodhouse, of 88, Mosley Street, Manchester. The competition was a local one, limited to the architects of Manchester and district. Thirteen or fourteen sets were submitted. Mr. Woodhouse submitted two sets, and it is noteworthy that he was successful in securing the first and second premiums. Mr. R. Knill Freeman was the assessor, and he placed the first four in the following order:—No. 1 (Experience) and No. 2 (Economy), Mr. Ernest Woodhouse; No. 3 (Spes), Messrs. Alfred H. Mills and Roger Oldham, 33, Brazennose Street, Manchester; No. 4 (Chapelle), Messrs. James B. Bowler and L. H. Dutch, 5, Cross Street, Manchester. The first three in his opinion were entitled to the premiums awarded, in the order placed above.

A Bridge on the River Brain at Braintree collapsed last Saturday while a steam-roller was passing over it.

Leighton House.—The Kensington Borough Council has declined to proceed further with the negotiations for the transfer of Leighton House.

To St. Wendron Church, near Helston, some additions have recently been made, including richly-carved stalls, detached desks and seats for the officiating clergy, a lectern and altar-rails.

New Buildings for Glasgow Parish Council are being erected in George Street from designs by Messrs. Thomson & Sandilands, architects. The following are the principal contractors:—Mason and joiner, Messrs. William Shaw & Son; slater, Messrs Hamilton & Co.; plumber, Mr. Robert S. Renfrew; plasterer, Messrs. Stevenson & Leitch.

"Old Mortality" was the name by which Mr. John Owen, of Stockport (who died recently), was known to his friends; for, like Scott's famous character, he revelled in gravestones, parish registers and all kindred records of human lives. The Lancashire and Cheshire Antiquarian Society elected him an honorary member in appreciation of his many services to local archæology.

Culham Training College, Oxford, is being extended by the addition of a new building, to be used chiefly for science. The new block, which is detached, occupies a site at the north-east corner of the main building. The building is of massive stonework, in Gothic style. Mr. J. G. T. West, M.S.A., of Abingdon, is the architect, and Mr. James Buckle, of Abingdon, the builder.

St. James's Church, Hereford, was destroyed by fire seven weeks ago and is to be rebuilt at a cost of about £4,000. The architects, Messrs. Nicholson & Hartree, propose, amongst other improvements, that there should be a thicker ashlar lining of the walls. They also propose to add a west door, the means of exit being at present insufficient; to enlarge the vestry, substitute oak for pitch-pine in the seating and roof timbers, and block floors instead of boards, raise the walls, and install a hot-water or steam heating apparatus.

Grecian Excavations.—Dr. Murray, in his second lecture at the Royal Institution last Thursday on excavations at Delphi and in the Greek islands, dealt with statues that had been discovered. Lantern slides were shown of a bronze charioteer, a marble statue of Agras, and a lion hunt of Alexander the Great which were found at Delphi; the statues recently recovered from the sea at Cerigo; and a bronze statue found at Pompeii. The French, said Dr. Murray, had accomplished one of the greatest tasks at Delphi, which was only to be compared with that of the Germans at Olympia, which must rank as the most productive.

Norman Arches in Chatham Church.—A meeting was held at Chatham recently to consider what course should be adopted with reference to the Norman arches recently discovered in pulling down a portion of the parish church for the purpose of rebuilding the old Georgian nave. A resolution was moved in favour of enlarging the scope of the restoration scheme so as to preserve the relics of the original Norman church; and it was stated that it would entail an additional expenditure of £1,000. The motion was carried unanimously. It was stated that contracts had been signed for the final section of the restoration scheme at a cost of £6,000.

Wakefield Philistines.—At a recent meeting of the West Riding County Council a discussion took place on the subject of the proposed widening of Kirkgate Bridge, at Wakefield. Three schemes have been under consideration, and it is feared that some interference with, if not the removal of, the ancient chantry will be inevitable. The chantry dates from the fourteenth century. The chairman (Mr. Milnes Gaskell) said the people of Wakefield did not seem to care much for anything unless it had a money value. He reminded members that there was formerly an ancient market-cross of much interest in the city. It had been carted away, and there was no proposal to restore it to a place where it would be an ornament to Wakefield.

St. Peter's Church, Fairfield, Buxton, is being enlarged at a cost of about £3,000 from designs by Messrs. Garlock & Flint, architects, of Buxton. Messrs. Alfred Hill & Brother, of Buxton, are the builders.

The Competition for the Hearts of Oak Benefit Society's New Offices has been awarded as follows: 1st premium, Messrs. Essex, Nicol & Goodman, 21, Waterloo Street, Birmingham; 2nd, Messrs. Meaby & Webbe, Jessel Chambers, Chancery Lane, W.C.; 3rd, Messrs. Lanchester, Stewart & Rickards, 1, Vernon Place, Bloomsbury Square, W.C.

Protest against Terms of Competition.—The Cardiff, South Wales and Monmouthshire Architects' Society have protested against the terms offered in a competition for a new chapel in Cathedral Road, Cardiff, which they consider inadequate. They express the hope that no member of their Society will take part in it, or in any other competition offering similar terms.

A Bronze Statue of Queen Victoria at Lahore, representing her Majesty seated on a throne in full regal state, erected by public subscription in commemoration of the Diamond Jubilee, was unveiled recently. The sculptor is Mr. Bertram Mackerrall. The Punjab Memorial Fund is to be devoted to placing a marble canopy over the statue, and has reached a total of £3,867.

The Society of Architects held a meeting last Thursday, when Mr. M. Sullivan read a paper on "Early British and Celtic Art," dealing entirely with its archæological and literary side. The secretary, Mr. Butler, announced the decease of Mr. J. A. Burton, of Ashton-under-Lyne, one of the first members of the Society; and Mr. E. C. Beaumont, of 78, Fleet Street, E.C., was elected a member.

Mr. Walter George Penty, architect, head of the well-known firm of Penty & Penty, of York, died last Thursday. He practised in the city for many years, and among the public buildings designed by him are the Free Library and the new Liberal Club. Mr. Penty was a Fellow of the Royal Institute of British Architects, and on more than one occasion occupied the position of president of the York Architectural Society. A "Men who Build" article dealing with his work appeared in our issue for November 7th, 1900.

The Selected Plans for the New Bluecoat Hospital at Liverpool, to be erected on a site at Wavertree, have been returned by the Charity Commissioners as being too costly (the amount works out at £280 per head), and it seems that a wholesale curtailment will be necessary; moreover, the old site in School Lane is scheduled in the Liverpool and Manchester Mono-Rail Act, and the Trustees may find themselves in the position of being asked for vacant possession of the old site before the new school is ready for occupation.

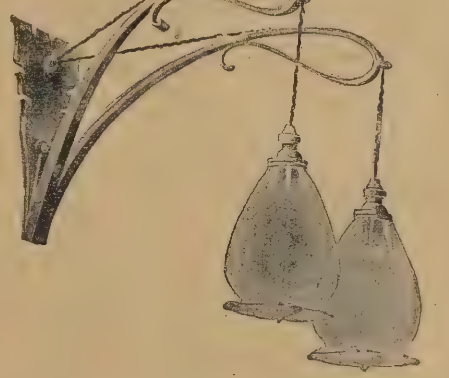
The Wolverhampton and District Architectural Association recently held its first annual meeting at the Law Library Rooms, Wolverhampton. The president, Mr. J. Lavender, occupied the chair. The officers for the ensuing year were elected as follows:—President, J. Lavender, F.R.I.B.A.; vice-president, G. H. Stanger, F.R.I.B.A.; hon. secretary, W. Edwards; hon. treasurer, J. Harrison Woller; auditor, W. J. Oliver, M.S.A.; ordinary members of Council, F. Hunter Lynes, A.R.I.B.A., T. H. Fleeming and S. H. Eachus, M.J.S. (London). The meeting concluded with an address from the president.

Northampton County School Competition.—The Governors of the Northampton and County Modern and Technical School have accepted plans for the extension of the school by the addition of chemical laboratories, lecture-rooms, boot and shoe shop, &c., and also for the erection of a master's house and boarding house on Billing Road, Northampton. A competition was recently held, and it was stipulated that the cost of the Billing Road buildings was not to exceed £4,000, and a similar amount for the extension and alteration of the present school. Mr. J. A. Gotch, of Kettering, was the assessor, and acting upon his recommendations the Governors, we understand, have accepted the plans prepared by Mr. Herbert Norman, of Market Square, Northampton, working in conjunction with Mr. McKewan, of Birmingham. A premium of twenty-five guineas has also been awarded to Mr. E. Danford, of Northampton, whose plans were regarded as the next best. There were about thirty entries.

Trade and Craft.

Electric-Light Fittings.

By this time we may expect that electric-light fittings shall be designed with that freedom which their use affords. Gas jets almost invariably demand a vertical termination, and other considerations (such as heat) restrict the designer to a large extent. But with electric light, which enables the lamps to be fixed in any position, such scope is possible that the design is ineffectual if it is nothing more than an adaptation of familiar gas-fittings; and, moreover, it exhibits a loss of opportunity which is much to be deprecated. Their conditions therefore being entirely without precedent, electric-light fittings should be uninfluenced by those for any other light. Many such fittings as these, designed with care and executed in a workmanlike manner, can be seen at the showrooms of the General Electric Co., Ltd., in Queen Victoria Street, E.C. Whilst being essentially modern, they do not exhibit the eccentric quaintness of some of our home manufacturers, nor the wild extravagance of Continental work; and in price they range from simple and artistic brackets at 4s. to articles costing £20 or £30 apiece. Although the Company's works are situated in Birmingham, the production of these designs is superintended by their designer, with the result that nothing whatever is lost by the separation of the head-office from the works. Some are finished in polished brass or copper, others in natural bronze, oxidised silver, and hammered iron (either black or finished in armoured steel). These finishes are sometimes combined with brass or copper, bright or dull, just as design or taste requires. The accompanying illustration shows a specimen of the work done by this company, who have various branches in different parts of the country—Glasgow, Newcastle, Manchester, Birmingham, Cardiff and Dublin. Their new Fittings Catalogue contains innumerable varieties, but the Company has a large staff of artists who are always engaged in submitting designs to suit particular requirements for public buildings, private houses, public contract work, &c. Amongst their contracts for street-lighting we may mention Rathmines, Pembroke, Queenstown, Hornsey, Fulham, Battersea, &c., and in this connection it is opportune to refer to their fitting for incandescent street-lighting when gas is replaced by electricity. The hood and reflector of the lantern have the incandescent lamps securely attached to it, and are so hinged that the whole of the upper part of the fitting can be swung back to facilitate cleaning and changing the lamps. The Company is at present engaged in supplying several large installations of this fitting, which has met with very generous approval among borough electrical engineers.



Window Glass.

In towns and cities, where the sky is made murky by smoke and buildings are high and closely huddled together, the difficulty of obtaining adequately-lighted rooms is very considerable, and tends to increase rather than to diminish. Various devices have been employed for making the most use of the light there is, and prominent among them is the patent prismatic rolled glass manufactured by Messrs. Pilkington Brothers, Ltd., of St. Helens—a glass which has been extensively employed with most satisfactory results. With ordinary glass the rays of light, falling almost vertically, are concentrated on the small space immediately inside the window, whereas by means of prismatic rolled glass they are diverted horizontally into the room and illuminate the whole of it. Its advantages in this respect are obvious; but, in addition, it is easily fixed, and is less liable to be broken than ordinary glass. Messrs. Pilkington also manufacture a wired rolled glass which has been proved to be an effective fire-stop, as well as a protection against burglary; which qualities have found for it a rapidly-increasing sale.

COMING EVENTS.

Wednesday, January 29.

Clergy and Artists' Association.—Annual General Meeting at 113 Cromwell Road, at 3.30 p.m.

Northern Architectural Association.—Council Meeting at 6.45 p.m. Mr. R. P. S. Twizell, A.R.I.B.A., on "The Development of Architectural Ornament," 7.30 p.m.

British Archæological Association.—Meeting at 8 p.m.

Thursday, January 30.

London Institution.—Mr. G. J. Burch., F.R.S., on "Colour Vision," 6 p.m.

Royal Institution.—Dr. A. S. Murray on "Recent Excavations at Delphi and in the Greek Islands,"—III., 3 p.m.

Society of Antiquaries of London.—Meeting at 8.30 p.m.

Leeds and Yorkshire Architectural Society.—Mr. W. H. Thorp, F.R.I.B.A., on "An Old Quarter of Paris," 5.30 p.m.

Friday, January 31.

Architectural Association.—Mr. C. Harrison Townsend, F.R.I.B.A., on "Originality in Architectural Design," 7.30 p.m.

Royal Institution.—Prof. A. Crum Brown on "The Ions of Electrolysis," 9 p.m.

Institution of Civil Engineers (Students' Meeting).—Messrs. J. C. Collett and W. H. C. Clay on "The Quay-Walls of Keysham Harbour," 8 p.m.

Saturday, February 1.

Sanitary Inspectors' Association.—Sir James Crichton Browne presides at the Annual Dinner at Holborn Restaurant, 6.30 p.m.

British Institute of Certified Carpenters.—Meeting at Carpenters' Hall at 6 p.m.; Council 3 p.m.

Edinburgh Architectural Association.—Visit to Archers' Hall and Craigmillar Park United Free Church.

Architectural Association.—First Spring Visit to Christ Church, Brixton Road (near Kennington Park), by permission of Prof. Beresford Pite, at 2.30 p.m.

Monday, February 3.

Royal Institute of British Architects.—Address to Students by Mr. John Slater, B.A. Criticism of Designs and Drawings by Mr. H. T. Hare. Presentation of Prizes. Election of Members. 8 p.m.

Liverpool Architectural Society.—Mr. Robert Pepys Cockerell on "The Life and Works of Prof. Charles Robert Cockerell, R.A.," 6 p.m.

Society of Arts (Cantor Lectures).—Mr. Samuel Rideal, D.Sc., on "The Chemical Purification of Water," 8 p.m.

London Institution.—Mr. C. H. Reilly, M.A., on "City Buildings, Old and New," 5 p.m.

Birmingham and District Clerks of Works' and Builders' Foremen's Association.—Mr. Albert S. Smith on "Ancient versus Modern Building," 8 p.m.

Society of Engineers.—Inaugural Address by Mr. Percy Griffith, 7.30.

Tuesday, February 4.

Cardiff, South Wales and Monmouthshire Architects' Society (Associates' Section).—Lecture by Mr. Edwin Seward, F.R.I.B.A., 8 p.m.

Society of Arts (Applied Art Section).—The Rev. Herbert Thurston, S.J., on "The History of the Rosary in all Countries," 4.30 p.m.

Institution of Civil Engineers.—Discussion on papers on "Sewerage Systems of Sydney, N.S.W.," and "The Bacterial Treatment of Trades Waste," 8 p.m.

Masters and Men.

The Limerick Carpenters' Strike, which has been in existence since May last, has just been settled on the basis of a compromise that the payment shall be by hour instead of by week.

A Dispute at Birmingham has arisen. Trade has been depressed recently, and the employers gave notice of certain reductions in wages. In the case of plasterers and masons a reduction of 1d. per hour was notified; masons' fixers it was proposed to reduce by ¾d. per hour, and other branches of the trade by ½d. per hour. Moreover, certain modifications in the rules are suggested, with a view to securing uniformity of weekly hours. Joint conciliation meetings will be held early in February.

The Bradford Joiners' Strike. — When the masons' strike in Bradford was settled recently it was hoped that the joiners' dispute would also be ended without further delay. Unfortunately there is no sign at present of any such accomplishment. Up to May last, when the strike commenced, the joiners were receiving 9d. an hour; and when the masters gave notice of a reduction of 1d. the men retaliated with a demand for 1d. increase. Since then the men have come back to 9d., and the masters have raised their figure to 8½d. The difference between 8½d. and 9d. still constitutes an integral part of the dispute. Of the original 500 men affected only about 200 remain out of employment.

New Companies.

Samuel Dowsing & Sons, Ltd.

Registered to acquire the business of Samuel Dowsing (deceased), formerly carried on at 26, Pembridge Road, Notting Hill, and elsewhere in London, and to carry on business as builders, painters, paper-hangers, and decorators, manufacturers of and dealers in building materials, gas, electric and sanitary engineers, ironmasters, dealers in coke, bricks, files, cement; as carpenters, timber merchants, &c. Capital £4,500 in £1 shares. The first directors are A. F. Dowsing and H. A. Hanson.

A. Shepherd & Co., Ltd.

Registered to acquire the business of sawmill owners carried on by J. W. Shepherd & Co, and the business of timber importers and sawmill owners carried on by A. Shepherd & Co. at Alexander Docks, Grimsby; to adopt an agreement with J. W. Shepherd and A. Shepherd, and to carry on the business of timber importers and merchants, sawmill owners, packing-case and rolling-board makers, joiners, cabinet-makers, builders, &c. Capital £7,000 in £1 shares. Registered office: Alexander Docks, Great Grimsby, Lincolnshire.

South Yorkshire Coal and Coke Co., Ltd.

Registered to buy and sell coal, coke and other articles of fuel, bricks, tiles, sanitary pipes, lime and other mineral substances; to acquire the goodwill of the business of the Lewden Colliery Co., and to carry on the business of colliery owners, miners and coal and coke merchants generally. Capital £5,000 in £1 shares. Registered office: Hunningley Villa, Stairfoot, Barnsley.

Whyman's Foundry Co., Ltd.

Registered to acquire the Hope Ironworks at Dallam Lane, Warrington, Lancashire, and generally to carry on business as metal founders, engineering in all its branches, mechanics and machinists, makers of ornamental fire-places and stoves, of metal colliery proprietors, lamp manufacturers, brick, tile and terra-cotta merchants, patent fuel makers, &c. Capital £7,000 in £1 shares. The first directors are Thomas Whyman, Thomas Baxendale and G. Baxendale.

An Architectural Causerie.

Mr. Bodley, R.A.

THE voting for the honours of the Academy is always followed with much interest, and last week's election of Mr. G. F. Bodley as an Academician will be regarded with unmixed satisfaction. No official intimation is ever given as to whose place is to be filled, and at the voting the impression prevailed that the vacant fauteuil was that of Mr. Norman Shaw, who a short time ago tendered his resignation (but has since reconsidered it); whereas in reality the vacancy was caused by the death of Mr. Onslow Ford. Several of the Associates received single votes in the first ballot, but serious support was given only to Messrs. Swan, Frampton, Macbeth, Bodley and Waterlow. All these artists went to the second or "blackboard" stage (having received at least four votes), and in this contest Messrs. Bodley and Frampton secured the greatest number of votes. In the final ballot, confined to Messrs. Bodley and Frampton, the architect beat the sculptor by a single vote, twenty-nine to twenty-eight: on which he is to be congratulated. Mr. Bodley, whose ecclesiastical work is too well known to need any special reference, became an Associate in 1882.

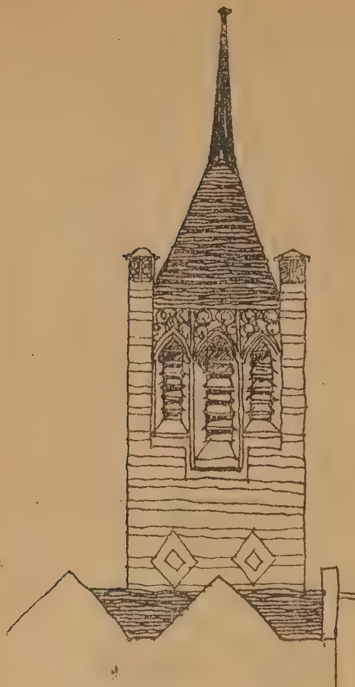
Coronation Decorations.

OUR civic fathers have begun, none too soon, their preparations for the Coronation; and there seems to be some real desire to retrieve our disreputable past in the matter of decoration. "The Times" in an excellent leader last week feels that "it is really time to do something better. What is the good of Royal Academies and National Schools of Art—the latter kept up at no small cost to the country—unless their influence can impose a systematic scheme which shall make London look, at the solemn inauguration of a new reign, not only gay but beautiful?" Gaiety and beauty are terms too often confounded. Gaiety can be accomplished with that blaze of crude colour vulgarly yclept the "Irish stew" decoration, a crash of discords productive of bibulence and "horseplay." Beauty is a tender chord of three notes of equal value—simplicity, dignity and harmony. It harbours a more chastened feeling than mere rejoicing, and thus is appropriate to the occasion. For the function has its solemnities. The coronation of the King is no honour personal to his Majesty, but a proclamation to the world of the majesty of the people in the person of their sovereign. The subject of the decoration should be a beautiful exposition of the fitting symbolisms of the ceremony. The Westminster City Council have begun rightly by adopting a set scheme of decoration for that district; and other councils will, it is to be hoped, follow this good example. So far only two schemes have been made public; but the occasion will doubtless call many more into existence. One by Mr. Vigers suffers much from over-elaboration and consequent loss of dignity. The idea of gilt figures poised upon coloured celluloid globes in which electric lights are burning sounds fearsome. Arches too should only be employed to emphasize particular portions of the route; they obstruct the view, and the route is too short to symbolize all the Colonies and public institutions and virtues to the detriment of the sightseer. Neither should one scheme be imposed upon the whole route, or monotony will quickly kill the effect. If each district adopts a distinct harmony of colour and design a pleasing variety will inevitably result. The second scheme, prepared by Mr. Selwyn Image for THE ARCHITECTURAL REVIEW, appears in the current issue of that magazine. It is a simple and dignified effort for the short route of the actual Coronation procession from Buckingham Palace to the Abbey. Not the least of its merits is the consideration which the author has accorded the Abbey. The most important point in any scheme is to fit the decoration to the buildings; not the buildings to the decoration. Westminster Abbey is "consecrated by centuries of unspeakable tradition through which his Majesty passes to his solemn dedication." To attempt to decorate it would be an impertinence. It must therefore remain in its own solemn majesty the most impressive piece of decoration on the whole route.

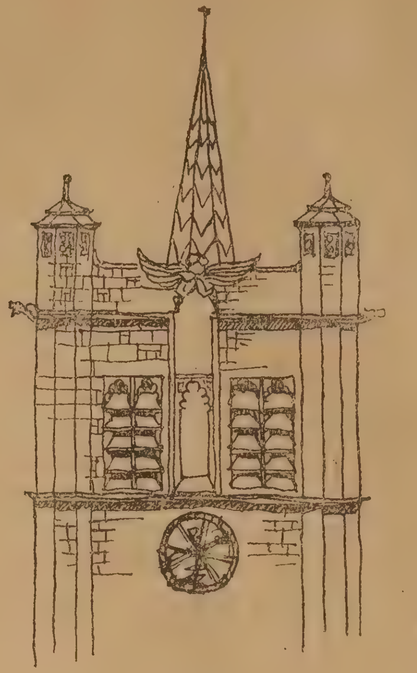
G. F. BODLEY, R.A.

The London Backyard.

BURNS'S cry that we might see ourselves as others see us is not always consonant with a truer or less biased opinion. Some time ago we were rather amused to read in a well-known American architectural contemporary that Londoners have one custom which our friends desire to see introduced into New York. Those who reside in or are familiar with London will doubtless learn with surprise that the backyards of the houses in the Metropolis are rendered attractive, decorated with flowers, and made to serve a purpose quite impossible to any New York backyard. "There is usually a balcony overlooking the yard, which is ornamented with growing plants until it might be taken for a conservatory. The imagination of decorators is allowed to exercise itself in all sorts of ways in making beautiful this part of a London house." It may be fairly assumed that the writer who gives this glowing account of the London backyard has never seen one: for the place is more often than not a depressing smoke-begrimed area which is not infrequently prejudicial to health, an opinion which is confirmed by Dr. Sykes in his recently-published book on "Public Health and Housing." Of the flower-bedecked balcony which might be mistaken for a conservatory we know nothing, and as regards the decorators' imaginations we should prefer to remain silent, though we cannot refrain from expressing pleasure in learning that they possess imagination.



(No. 306.)

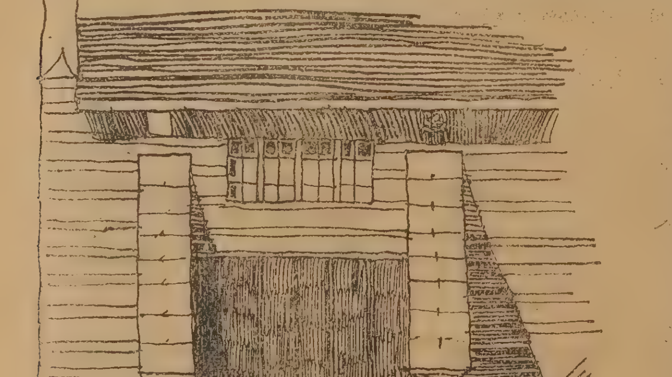


(No. 302.)

BIRMINGHAM SCHOOL OF ART.

Annual Exhibition.

THE annual exhibition of students' work in connection with the Birmingham Municipal School of Art is now being held in the rooms of the Society of Artists, and remains open till February 7th. Though the subjects set are good, the architectural section (which is under the able direction of Mr. W. H. Bidlake, M.A., Mr. C. E. Bateman and Mr. Herbert T. Buckland) is not up to the standard of former years. Of the designs for a village church there are only three worth mentioning. That by Mr. W. Jones is fairly good, but the author, in his effort to be original, goes too far, and the pointed arches (like that of the porch, No. 305) are not pleasing; the tower, however (No. 306), deserves mention. The design numbered 301 is, if anything, a better design: the tower is shown among the accompanying illustrations (302). No. 297 is a neat set of ink drawings, with an ordinary plan. There are several good designs shown for a village railway station, that by Mr. Augustus S. Reeves being the best; moreover, his drawings are straight-forward, and not "faked" like those of several other students. Another good design is that by Mr. Norman E. Twist; the footbridge across the lines is very simply and pleasingly treated. No. 283, by Mr. Ernest C. Harrison, is also good. The subject of "A Mission Hall" has drawn a good many students, and of these the design numbered 294 (by Mr. E. L. Cashmore) is specially worthy of note. Mr. S. N. Cooke's design (No. 311) for a lodge to a country house is attractive, though it could be greatly improved if the blue brick were omitted and stone used in its place. Mr. F. Goldsbrough's design would look decidedly better without the "Voysey" buttress, but the chimney stack is good. The measured drawings shown in the exhibition are satisfactory. Mr. Norman E. Twist sends some fine pencil sketches and drawings of favourite parts around Wells, and Mr. Ernest C. Harrison exhibits work from the neighbourhood of Oxford. No. 321 sends in a measured drawing of a modern public-house!—a strange work to select. On the whole the architectural exhibition is not so good as the decorative section, where the design by No. 342 for a chimney-piece and the cast model (No. 204) of a statue of Queen Victoria are most deserving of praise.



PORCH TO A VILLAGE CHURCH, BY W. JONES (No. 305).

ARCHITECTURAL ASSOCIATION.

"ORIGINALITY" IN ARCHITECTURAL DESIGN.

By C. HARRISON TOWNSEND.

A MEETING of the Architectural Association was held on Friday evening last at 9, Conduit Street, W. (Mr. Howard Seth-Smith, president, in the chair). After the minutes of the last meeting had been read and confirmed, Mr. H. H. Christie, Mr. A. L. W. Sampson and Mr. R. S. Wilkinson were elected members of the Association. It was announced that the Second Spring Visit would take place on February 15th to the Victoria and Albert Museum, by kind permission of Mr. Aston Webb, A.R.A.

The president then announced the following additional donations to the New Premises Fund:—

	£	s.	d.
Merchant Taylors Company - -	105	0	0
M. Garbutt - - - - -	10	10	0
A. T. Walmisley - - - - -	5	5	0
E. H. Parkes - - - - -	2	2	0
"A.A. Student" - - - - -	1	16	6
W. E. Hewitt - - - - -	1	1	0
D. A. Forster - - - - -	1	0	0
	126	14	6
Donations previously announced	3,589	18	0
Total - - -	£3,716	12	6

The president announced that a class on perspective (Mr. W. G. B. Lewis, lecturer) would commence on February 12th and a class on ventilation, lighting and heating (Mr. Max Clarke, lecturer) on February 13th.

Mr. C. Harrison Townsend, F.R.I.B.A., then read his paper on "'Originality' in Architectural Design." He said:—

I deplore the inefficiency of the presentment of this subject, the more that I feel it to be quite one of the most important that you could meet to consider. For it does not propose to add to minds perhaps already largely stored another item or series of items of knowledge, but it offers for consideration what to do with the sum total of all the learning you have up to now acquired and will in the future acquire. And it suggests the subjection of the isolated facts of learning to a synthesis that shall resolve them into one organic whole.

Lectures on styles, papers on materials, demonstrations on methods, these and the daily experiences of your work all help to fill your minds with the data of certain indispensable knowledge. Yet even profiting to the full by these opportunities, and bringing to them even the most unflagging industry and the most retentive of memories, you are then face to face with the question of how to get the most complete outcome from this mental equipment. And the doubt arises whether a store of facts and a mass of knowledge are all that go to the making of an architect. Does the fact that you are—even generously and widely—educated, that you have at your finger-tips any amount of knowledge of materials and construction, and that you possess a full acquaintance with the historical remains of architecture handed down to us from other days—does all this do more than make you *ready to be* an architect? Does it, as a matter of fact, constitute you one in the proper sense of the word? And unless something breathes these dry bones of knowledge and tradition into life, is their possessor more than a skilled "practitioner"—a thoughtful and cultivated "professional man"?

I am here by no means raising the tattered banner on which is inscribed the wearying question "Is architecture an art or a profession?" I care little whether it be an art or a profession, or, for the matter of that, a trade. Whichever we term it, however, a man's fitness to be and claim to call himself an architect are not to be estimated and gauged by the measuring-standard of what he has learnt. It is not by what he knows, but by what he does with what he knows, that he shall be judged. It is for him to throw into the crucible of his own nature all his learning and all his knowledge, there to be fused and made one, and out of that melting-pot to draw an ingot that is to be stamped and shaped as his own personality, his own individualism, shall determine. As Marcus Aurelius says: "Is it not a grievous thing that an architect shall respect the course and mysteries of his profession more than the proper course and condition of his own nature?" That is to say, that too great a regard for that course and those mysteries, or, to put it otherwise, the attachment of undue importance to formulæ and rules, causes a positive atrophy of the imaginative and creative faculty, by which an artist—the architect as well as the painter and sculptor—should claim to be appraised.

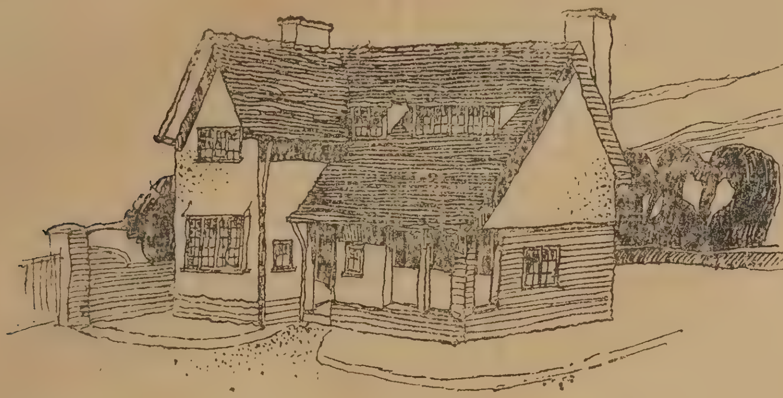
> "To follow foolish precedents, and wink
> With both our eyes, is easier than to think."

Yet precedents and traditions must need exist and endure in every art, and it would be presumptious to claim to be in art absolutely free, and to have shaped oneself rather than to have been made by the great thoughts and the great men that were of old time before us. There is no logical standpoint for him who disclaims and disavows all reference to, all dependence upon, all reverence for the past, and whose ideal is the substitution of his own ignorant lawlessness for the lessons handed down to him from other times. Such a one, I imagine, would without remonstrance accept and adopt the term "anti-historical" applied the other day in one of our weekly papers to express the aims in art of one of those architects whose views I am trying to put before you now, and could not consistently rejoin that he claimed to be individual in expression—*not* original and creative. Nor could he further maintain, as that criticised architect would, that he was in fact *more* truly historical and following *more* closely along the lines of architectural evolution than the many mimics of the forms into which architects of distant countries or of bygone days have cast their thoughts and their ideals.

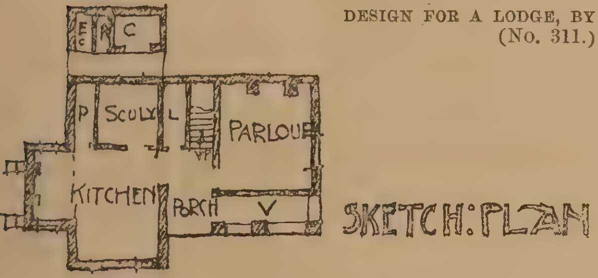
Here, let me ask, is there justification for alleging that any—or, at all events, let me say that any considerable number of—architects have in set terms foresworn allegiance to tradition, and have claimed the right to apply the word "original" to their works? I think not. Individual in method of expression, yes; non-resurrectionists of long-since dead and buried styles, yes; haters of mimicry of earlier forms that were expressions of earlier wants and needs, again, yes. I know those who are glad to come under those categories, and I venture to think that in their hands lies the future of our art.

Yet, remember, that in thus doing your best to make your architecture speak To-day rather than the Past, you are not to strive, of set purpose, to be what you or others may call "original." As Lowell says in one of his letters, "When a man *aims* at originality, he acknowledges himself unoriginal." You will find it both grand ideal and hard task enough to try to let your work reflect you yourself and to give it a personal and individual character. If it thus bears your own impress, what more "originality" need it have or can it have?

But this quality must come of itself; it must result not from the attempt to do what other men have never yet done, but from your wish to shape your work so because it seems to you the best solution of the problem before you. And, having worked out this—your own—solution you neither adopt nor, on the other hand, repudiate it, because others have arrived at this result before you.



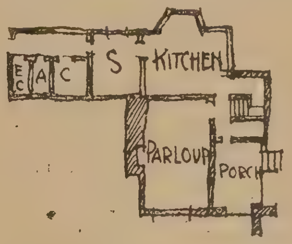
DESIGN FOR A LODGE, BY S. N. COOKE.
(No. 311.)

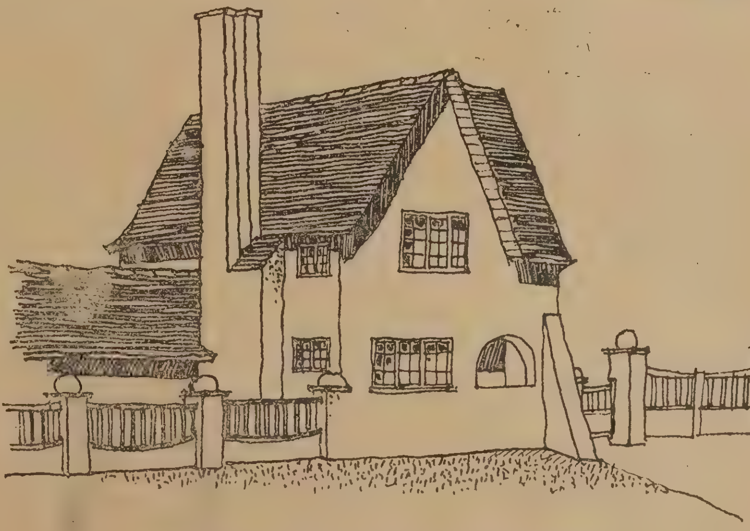


We have in architecture, as I have said above, a speaking living tongue, and if the thick mists of custom and conventions allowed us to see it, nothing can be more illogical than for us of to-day to borrow the language of Byzantium or Florence or Amsterdam in which to give our message in this Year of Grace 1902, or to rely upon a thirteenth- or fourteenth-century vocabulary as a means of expressing architecturally our own religious needs and aspirations. While our language, as we now read or speak it, comes to us enriched by that of other days, it yet has the distinct stamp and impress of its time, and to express our wants or tell our tale one to another we do not in book or conversation deliberately adopt the spelling or the speech of Chaucer or of John Florio or even of Addison.

Yet is not this precisely what we do in architecture? Is not the measure of praise bestowed upon a modern building in exact proportion to the faithfulness with which its designer has worked on the lines of other times—Mediæval, Elizabethan, Georgian, or what not; or to the closeness with which he has imitated the architecture of, I know not what country—Holland, Italy or France? Is a man ashamed, as he should be, when he is told that his building (*his*, mind you, finished to-day or yesterday, in 1902, in 1901) is "so faultlessly Elizabethan that it might well be taken for an old building of that date?" Does he feel insulted, as he should, when he is assured that "in general design as in every detail his church is conceived and worked out in a thirteenth-century style?"

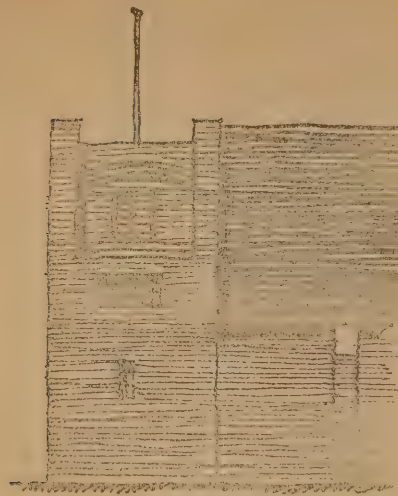
I know it will here be said that there are less extreme cases than these, and I shall be reminded that there exists that vaguely qualifying phrase, "a free treatment" of such-and-such a style, which is supposed to represent a saving grace, and to oblige us to approve a design which is not, like those others, all copyism, but one with, say, 75 per cent. of imitation and 25 per cent. of "free treatment." This seems to me to be a distinct concession towards the point of view I am speaking of, and even this modicum of freedom is to be welcomed, and we ought to be thankful for, at any rate, such proportions as I have suggested. Yet these might conceivably be reversed if the architect's mental attitude when face to face with a problem of design were different to—and, as I think, more logical than—the usual one, and one might then hope to find, let us say, 75 per cent. of spontaneous individual personal feeling in the design, and the 25 per cent. residue, if it did happen to be reminiscent of other and preceding work, would not, at all events, be so because of an avowed desire to recognise closeness to the designs of earlier men as the ideal towards which one should strive.





DESIGN FOR A LODGE, BY F. GOLDSBROUGH.

An architect may (and I am, as I have said before, glad to say he usually does) tone down the rigid exactitude of a sheer copy by more or less admixture of his "free treatment." But how often does he not sit down at his drawing-table with the acknowledged intention of producing a "Gothic design"—a "Renaissance design" (both of them with or without that wonderful "free treatment")—or, indeed, as it sometimes happens to-day, a design in which all architectural graces are to be laboriously and effectually omitted altogether in the name of simplicity? And selecting from a well-stored memory—I refrain from suggesting dependence



(No. 287.)

upon Kodak, or reference to sketch-book—a certain form or fashion or style, does he not proceed to clothe his building with the particular material his mental pattern-book suggests, and to rely for his design more upon the achievements of the past than upon his own invention and his own imagination of the present?

I have said more than once he may refer to and ask the past to help him to a solution; he must not depend on it to find him that solution.

In literature, a few years ago, we were all keenly touched to hear an American critic of much note tell us that "all the tales have been told." He was more wrong than even most makers of epigram; and we felt that while men and women are, and while lives are happy or are sad, and while hopes are hoped or frustrated, and while hearts are blithe or breaking, there are still at each turn and every moment tales, comic and tragic both—unwritten, it is true, but there, and only waiting the writer.

And in our own art, are all the tales exhausted, and are we at best to repeat—in perhaps slightly, very slightly, different words—those that our fathers told, with here a change of adjective and there an added or a diminished emphasis, with this trifling omission, that small addition? Did our tales, ours as architects, stop short a hundred years ago, leaving us tongue-tied and silent unless we speak a Georgian speech and talk in the eighteenth-century words of our great-grandfathers? (I do not stop here to ask if even their architectural utterances were the best to which they might have attained, and if they—and their fathers in turn—were not, at most, speaking in a kind of dog-Latin—or dog-Roman rather—more false and unnatural even than the would-be Classic Pastorals and Eclogues of their literature. That would be to discuss what *their* aims might and should have been. I am considering what ours of to-day should be.)

As their language helps us of to-day to speak, so their architecture is an element in our education; and education should merely fit us for that design for which we too often find it substituted. If in a given building we have, for instance, to carry a weight, let us admit that our beam or bressummer need not necessarily be borne by a column modelled, with more or less faithfulness of copy, upon what the Greeks or the Romans or the builders of the Middle Ages have done before us. It is *our* weight, to be carried in *our* way, and it is for us to think out the problem of how best to make and shape and fashion the column to do *our* work, not to solve our difficulty by borrowing their method.

Sydney Smith's profane one, who was, like Talleyrand's *père de famille, capable de tout*, and who even went so far as to speak "disparagingly of the equator," was, I imagine, the most orthodox of persons compared with him who, in this room and to this audience, ventures to breathe a doubt as to the supremacy and all-but-sacred character of the Corinthian column, and whose architectural agnosticism looks with the same unorthodox eye alike upon the "Five Noble Orders of Architecture" and the various "Periods" under which archæological architects have tried to catalogue Gothic architecture.

Such a profession of want of faith is sure to be met—I have heard it over and over again—by what is supposed to be a crushing *ad hominem* rejoinder. The sceptic is told that till he shall, in the first place, himself produce, or, in the second, shall put forward evidence that it is possible for himself or others to produce, a column that shall approach even within measureable distance of the Greek model, it were better that he held his presumptuous tongue, and—like his interlocutor—were content to recognise that the Corinthian order gives architects the best and highest and final expression of the column possible. And, further, that thus recognising it, he should feel happy and grateful for so good a thing to copy. (Of course, by the way, he need not adopt the actual word "copy," but may use a more refined method of expressing the same thing, and refer to it as his "precedent" or "the source of his inspiration.") In answer to which I would urge that, while no art is entirely and absolutely "upon all fours" with another, and admitting that analogy is generally a somewhat specious method of argument, I think it quite a fair and legitimate request to ask you to put to yourselves for a moment this problem of dependence upon the great achievements of the past in the terms of another art. Let us see, for instance, how it looks when presented to us, not as an architectural, but as a literary question.

There were great Greek architects—say, for example, Callimachos, or Scopas or Ictinos—who wrought with their highest power and skill upon a certain factor in design common to them all—the Corinthian column—and produced examples of this beautiful feature which are recognised as reaching the highest possible point of attainment of which it is capable. They obeyed at the same time all the necessary conditions—their column has base, shaft and capital; it has proportion; it suggests strength where that quality and expression are called for, and elegance where æsthetic claims demand it. The result is beautiful beyond question.

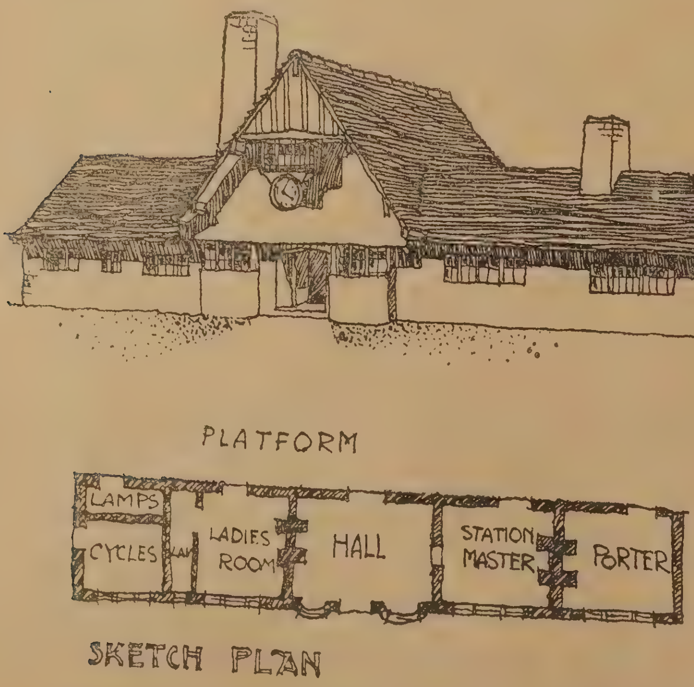
Well, let us now, as our parallel in literature, turn to poetry, and taking the sonnet let us posit, for the sake of my illustration, that Shakespeare, Wordsworth and Keats have written the finest and most perfect verse in this particular form of which our language can boast. And for the further purposes of my argument I take these, the three greatest writers of sonnets, as the equivalents in literature to those who created the most perfect productions of Greek architecture. Then, if we regard both these great architects and these great poets from the same logical standpoint, it is no straining of argument that puts us into the position to paraphrase what we already say to the modern architect, and to cry to the would-be sonnet-writer of to-day, "Hands off! The most supreme shape in which you feel your thoughts could mould themselves is not for you! Do you forget that through Shakespeare or Wordsworth or Keats the greatest sonnet that the world has seen has already come into being? With perfection thus attained, why ask us to be satisfied with less? Are you then so presumptuous as to offer us your own poor thoughts in your own halting words simply because they *are* yours and because you feel that only thus can you speak your own message? No! The best is written, and for you remains at most humbly and reverently to offer us more or less imitative variants of that great work."

Do not misunderstand me on an important point in connection with this illustration. I am taking the sonnet—a form common to all poets—as the parallel to the column in general—a feature common to all architecture. You cannot allege that my position is the ridiculous one that because great men have used them we ought to abandon the sonnet-form in poesy, or the column in our own art. My point is that in architecture we copy—whether we call it so or not—what we consider the very finest example of the past, calling the result architecture, and it would be but a mere "parity of reasoning" if we were in the same way to copy absolutely the most perfect sonnet of Shakespeare and to call that result our poetry. It should influence every poet; no poet should copy it. The column of Ictinos should influence every architect; no architect should copy it.

Or let us imagine, again, a poet of the past who has breathed into his verse the fullest and most satisfying expression of the mystery and beauty of the dawn, and whose noble lines reveal to us, in highest degree, its very soul and essence. Is, let me ask, the wonderful and supreme beauty of this achievement of former days to silence, as if it were sacrilege, the voice of later poets who also hear what Nature has to say when another day is born? Are they to be told that it is for them presumption to try to sing the dawn, and that its spirit and sentiment, and charm and beauty have been, once and for all, seized hold of, and cast into so perfect a form that it is rank profanation to touch the theme again?

It is only in bricks and stone that we express our wants and ideals by means of borrowed Elizabethan phrases rather than in our vernacular; only in our churches that we imitate the archaism of Chaucer—an "English undefiled," it is true, but his of the fourteenth century, not ours of to-day.

I am not contending that copyism does not find its way into other arts than ours, but I do urge that at most they copy the methods, the



DESIGN FOR A VILLAGE RAILWAY STATION, BY AUGUSTUS S. REEVES.

technique, the principles of other men and other schools; they do not, like us architects, copy the actual work. Our only invention is in the rearrangement of other men's thoughts; our only thought how to re-dispose other men's inventions. And even if in some degree imitation and copyism exist in the other arts, ours is the only one *based upon it.*

We do not and we will not call it copyism or imitation, but we use a hundred-and-one qualifying expressions to soften down those words. We talk of our "precedent," our "source of inspiration," of the "freedom with which such-and-such a style has been treated," of the "fresh and clever way in which the architect has dealt with his limitations of style," and so on, and so on. But all these phrases do is to express that the work is not a strict copy; that it is but in part imitation; that the pretence is dropped at times and it is not all mimicry. They do but mean that, here and there, the architect was tempted to think for himself. As a matter of fact, these occasional lapses into heterodoxy are regarded with a good deal of that suspicion natural to the orthodox, and the regular practitioners are pained and shocked at any departure from those recognised and traditional formulæ which they themselves have christened architecture.

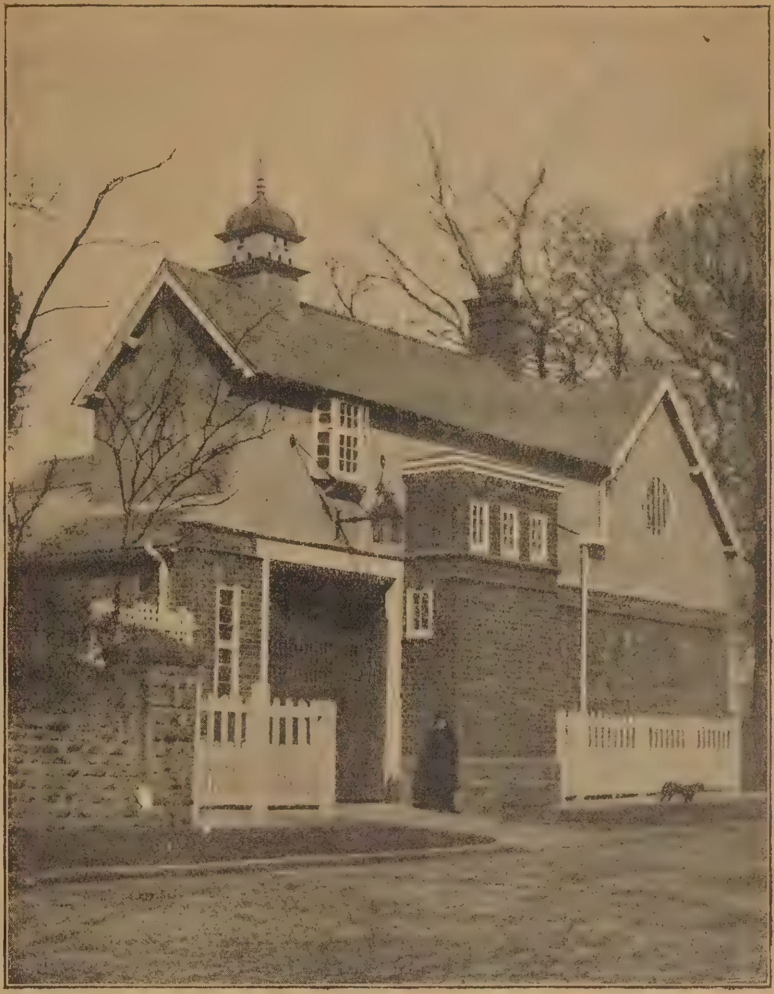
Yet, for myself, I welcome these lapses, and would fain see them more frequent and their scope wider, till at length the "free treatment" spread over the whole building.

You will remember that I spoke above of designs which were so far daring as to show a quarter of individual and spontaneous thought, as compared with three-quarters of dependence upon recognised style. I advocate no impossibility, or unattainable ideal, when I plead for at least a reversal of those proportions, and that your work shall show your own personal thought and individual ideas as by far the larger element in the design. Face your design—your plan or elevation, or tower, or door, or cornice—as your own work which you must do in your own way, resolving to infuse it with the qualities you feel it ought to possess to represent *you*, and not with those that memory points out as being necessary to some selected style.

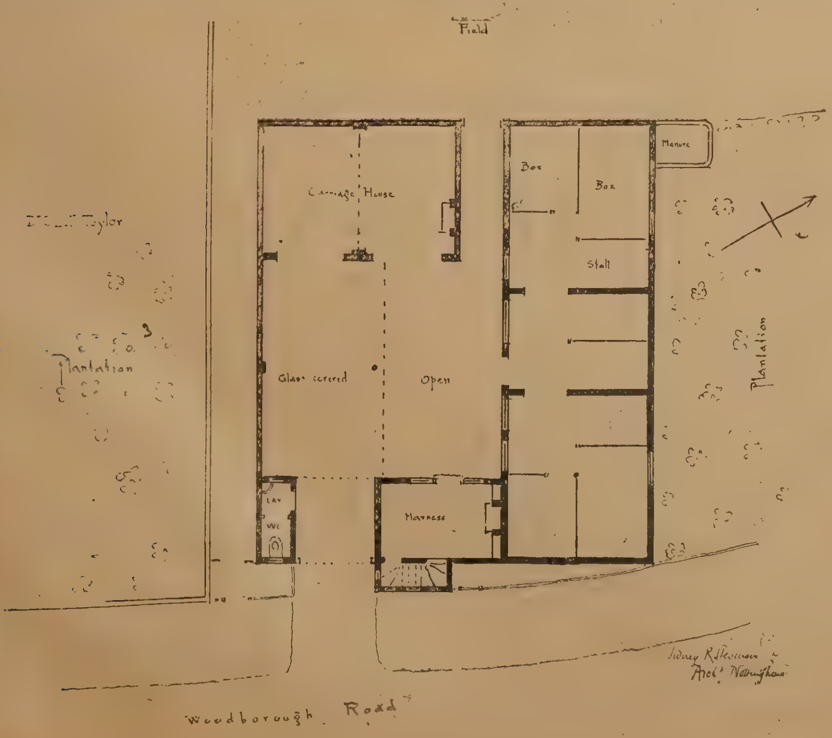
I am no despiser and contemner of that accumulated experience we call tradition, and in asking for our release as architects from the necessity to conform to the styles of other days and countries I recognise as much as anyone the need of education, and that acquaintance with the highest achievements of other men that best fits us to express ourselves also at our best. As Sidney Lanier puts it, "Once for all, in art to be free is not to be independent of any form; it is to be master of many forms."

I am not asking you, as I said before, to try to be "original," but I *am* begging you not to copy. And to start intending to shape an architectural design upon the lines of any style must, of necessity, imply copyism on a greater or less scale.

It is in placing individualism, fully equipped by education, before stylism that one sees the possibility of architecture becoming once more a speaking tongue, by the means of which man's wants and ideals of to-day shall be clothed in the outward shape those wants and ideals ask, and not in the worn-out trappings of the past or the mouldered cerements of times for ever dead.



STABLING AT NOTTINGHAM FOR DR. C. BELL TAYLOR. SIDNEY R. STEVENSON, ARCHITECT.



Let me conclude with one of E. Wharton's apologues:—

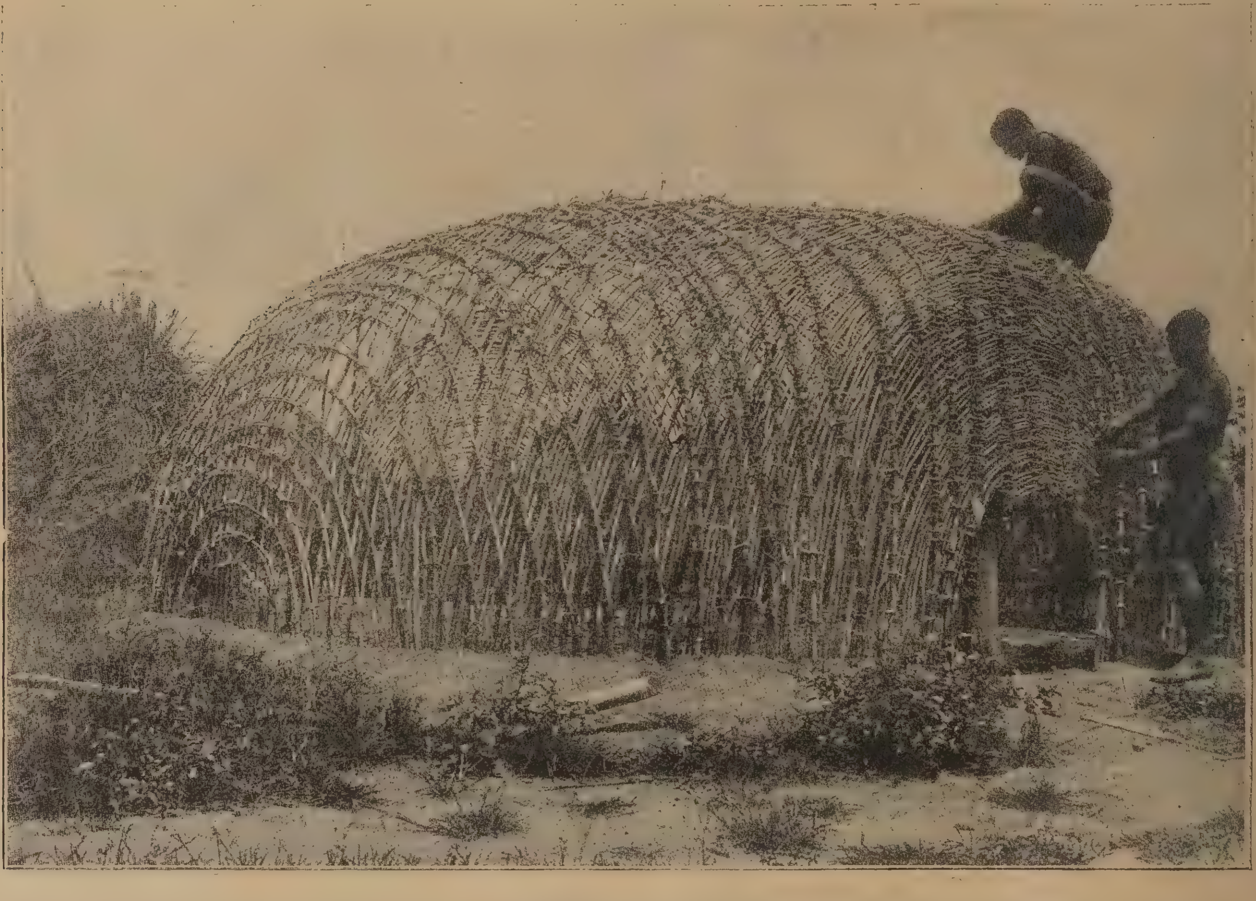
"There was once a man who had seen the Parthenon, and he wished to build his god a temple like it. But he was not a skilful man, and try as he would he could only produce a mud hut thatched with straw; and he sat down and wept because he could not build a temple for his god. But one who passed by said to him, 'There are two worse plights than yours. One is to have no god; the other is to build a mud hut and mistake it for the Parthenon!'"

To which I add this rider: "Nay," said another passer-by, "you would have built a better temple to your god had you had an ideal of your own, and so no need to copy—even the Parthenon."

The Discussion.

Mr. Henry T. Hare, F.R.I.B.A., in proposing a vote of thanks to the lecturer, said that, although it would be agreed mere copyism was demoralizing, at the same time he did not think Mr. Townsend in condemning all copyism looked at the matter so broadly as he should. The development of architecture was not a matter of a few years or even generations, and he did not think the Victorian architects would come to be regarded as such utter copyists as we might now consider them to be. All architecture was based on the study of tradition and what had gone before, and in every generation the majority of men had only mediocre capacity in translating their studies into their work, which would be more or less a copyism; yet there would always be one or two men having sufficient individuality to produce something living. He did not think that one would call Street a copyist, though he did work in the Gothic style; and nobody would say that Cockerell was a mere copyist. The men of the Renaissance revival, although working more or less on the lines of Classic architects, could not be termed copyists: the work of Palladio and Inigo Jones was full of originality. Everyone could not be expected to possess sufficient individuality to create original ideas, and he thought it safer for the majority that they should confine themselves to work on purely traditional lines rather than to strike out new paths for themselves. At the same time he was of opinion that Mr. Townsend's paper would do good, and students should not forget that no amount of originality could take the place of the hardest study.

Mr. Francis Hooper seconded the vote of thanks. He also felt that there was some danger in entering upon new paths. After Mr. F. Lishman had made a few remarks, Mr. Alexander Wood spoke. He thought that as Mr. Townsend had based his claims for originality on the study and grasp of the old, he was on the whole quite just; but he doubted whether one could be really original. Even if one avoided books there would be an unconscious influence from the past. He also doubted whether it was possible to absolutely copy, as every new need demanded a new treatment. The president also spoke and Mr. Townsend replied. The meeting then terminated.



NATIVE HUT BUILDING IN ZULULAND.

The Stabling at Nottingham illustrated on the previous page was completed last year for the noted occulist on land adjoining his residence, Mapperley Park, Nottingham. The entrance archway opens into the covered portion of a central quadrangle. Stabling is provided for eight horses—four loose boxes, four stalls—and a carriage house with ample room for four large four-wheeled carriages. Convenient rooms occupy the upper floor over the harness-room and archway. The building was erected by Mr. J. J. Adams from designs by Mr. Sidney R. Stevenson, architect, Nottingham. Messrs. Lewis & Grundy, of Nottingham, supplied the radiators and open fireplaces, as well as the stable and harness fittings. A mash-room, with range, copper, sinks and "fuel," shown on the original plans, had to be omitted owing to the proximity of the house.

Engineering Notes.

The Government's London Water Bill for the purchase of the eight water companies and the constitution of a Water Board of sixty-seven or sixty-nine members, was read a first time in the House of Commons last Thursday.

New City Subway.—A public subway is to be constructed between the Bank Station of the Central London Railway and the Lombard Street Station of the City and South London Railway, at the level of the booking-offices.

A New Electricity Generating Station is being erected by the Manchester Corporation. The building will cover an area of more than eight acres, and, with its sub-stations, will rank as one of the largest erections of its kind in Europe. The estimated cost, when 27,000 horse-power has been provided, is close on a million pound. Plant will eventually be laid to produce 70,000 horse-power.

Society of Engineers.—At the meeting held on Monday evening last, after the premiums awarded for papers read during the past year had been presented by the retiring president, Mr. Charles Mason, the newly-elected president, Mr. Percy Griffith delivered his inaugural address, in the course of which he dealt with water-supply and gas engineering.

The Acetylene Association has now been formed for the advancement of acetylene gas engineering and manufacture. Austria, France, Germany, Italy, Switzerland and the United States have already formed important associations specially devoted to the acetylene interests. England, although the last to establish such an association, was the first country in Europe to commercially manufacture carbide of calcium. "The Journal fo Acetylene Gas Lighting and Carbide of Calcium Review" is the official organ of the Association. Mr. Lacey Downes is the temporary secretary, and his offices are at 11, Ironmonger Lane, E.C. The subscription for ordinary members is one guinea per annum.

New Electric Lighting and Dust Destructor Works at Bermondsey have just been erected by the Bermondsey Borough Council. The new works are situated in Spa Road, at the rear of the town hall and public baths, and they occupy an area of about 1½ acres. The buildings consist of a destructor-house, an engine-room containing the generating plant, a pump and fan-room, an accumulator-room and offices. The destructor-house is specially designed with a view of giving adequate ventilation. It consists of six cells, each having 26 sq. ft. grate area, and capable of destroying 50 tons of refuse in twenty-four hours. The continuous-current system has been adopted. The charge for electric lighting will be 6d. for the first hour and 3d. for each hour afterwards, based on the *minimum* demand system. For motive-power purposes the charge will be 2½d. per unit. In the borough the three-wire system of mains has been adopted, and the feeder mains are at present four in number. With regard to the public lighting there are at present seventy-one standards erected, supporting 10-ampère double carbon arc lamps and incandescent lamps. At 12 o'clock every night the arc lamps are permanently turned out and the incandescent lamps are lighted. The new stables, when completed, will afford accommodation for sixty horses. At present only fifty-four stalls are fitted up. The new depôt also includes workshops, stores, offices and other buildings for municipal purposes. The residuum from the destructor will be used for making pavement flags by means of an electrically-driven hydraulic plant. The machine turns out flags at the rate of twenty-five per hour at a very low cost. The clinker is ground very fine, mixed with a due proportion of cement, thoroughly incorporated, and then subjected to a pressure of 1,000lb. per sq. in. and afterwards allowed to dry.

An Architect Magistrate.—The Lord Chancellor has appointed Mr. George W. Webb, F.R.I.B.A., of Reading, a magistrate for the county borough of Reading.

A Zulu Hut.—The illustration on this page of two Zulus completing the framework of their hut explains very clearly the methods adopted, and is particularly interesting as showing the elementary architecture of savages, which one may fairly judge to be like that of our progenitors.

PARIS: PAST AND PRESENT.*

By HAROLD SMITH, A.R.I.B.A.

ASSUREDLY the city of Paris is greatly indebted to the Seine—the "nursing Seine," as old Father Du Breul rightly calls it—for the infant Paris was cradled amidst its waters. Yes! Paris had its birth in the ancient island of the cité, now marked by the towers of the queen of the French cathedrals, and for several centuries remained invulnerable in its island state. Then, too straitened by its unsularity, it crossed the water on either side. The river then divided Paris into three great divisions—the cité on its island lying in the middle of the stream, like a ship stranded in the mud; the Ville on the northern, and the Université on the southern bank. The lower walls of the high houses soon hemmed in the river, so that its waters were hardly visible; the river disappearing under the bridges, and the bridges being lost amid the houses. At night chains were stretched across the openings in the ramparts where the river entered and left the city, thus preventing all hostile intrusion.

Historically, then, the centre of Paris is the island in the Seine on which stands the cathedral. There are certainly few finer architectural pages than its front, and what is said of the front must be said of the whole church. Everything is complete in this art, at once logical and well-proportioned. But the Paris of Notre Dame was complete only for a moment. Hardly was the tower of St. Jacques-de-la-Boucherie finished, ere they began to rebuild the Louvre. Thus the Gothic Paris, which had superseded the Roman Paris, has in its turn disappeared, and given place to the Renaissance Paris.

The Renaissance in its turn is divided into phases. It is thus that we have the Paris of the Medicis and Valois at the Luxemburg—early product of Italian influence; that of the Bourbons at the Invalides—the drawings for which so excited the ardour of Sir Christopher Wren; that of Napoleon at the Vendôme Column—a bronze shaft of captured cannon; and that of the Restoration at the Bourse. The Revolution alone has left no memorial: its leaders being but "the austere architects of ruin."

Obviously there must be a limit to the energy that a race can at any time put forth; if more be expended in one direction, less can be applied in another. Hence, during the Revolutionary period, there was a marked lack of artistic production. Moreover the closing years of the eighteenth century had seen a great decline in taste and spontaneity of invention. It is true that France had been more active in the decorative arts than her neighbours; a better and more refined taste, a livelier imagination, is still to be traced in the Petit Trianon. But this revival had no scope for architectural expression. So it followed that, as there was no natural sap of inspiration, those who still loved the beautiful sought to revive the fallen estate of architecture by reproducing the glorious fabrics of ancient Rome. This Roman revival culminated in the church of the Madeleine. It, indeed, produced several very stately facades, but did not reform architecture. It was but a fashion, an artistic exotic, corresponding to no change in life or taste.

The Neo-Grec movement was the first sign of the revival from the exhaustion engendered by the Napoleonic wars. It greatly influenced the work of such great artists as Lefuel, Garnier, Ginain and Vandremer. The residence of the last-named in the Rue d'Antin displays at once the powers and limitations of this pseudo-Pompeian revival. It could purify detail: it could not reform design.

The accession of Napoleon III., however, created a new era of architectural activity. Napoleon surpassed Louis XIV. himself as a patron of art, and the Baron Hausmann outdid Colbert. Assuredly, our age has seen nothing to equal the change then wrought in the aspect of Paris. The result was a genuine awakening. The Emperor himself, firmly adhering to his motto, "le carriére ouverte aux talents," did not dictate to his architects. Now, seeing too clearly the faults of the style which thus evolved, it is impossible to fully appreciate the greatness of the advance; or to rightly estimate the debt we owe to the Ecole des Beaux-Arts. For we are undoubtedly its debtors, both for the training of French and foreign artists, and the upholding of sound principles of design and wise standards of taste. Moreover, under the influence of this awakening the Ecole began to teach the doctrines of a more enlightened liberality. Hence the great external variety displayed in the designs of its students, in the main lines of which are so much order and uniformity.

During the second Empire, besides the New Louvre under Visconti and Lefuel, another undertaking of the first rank was commenced. This, the Nouvel Opéra, is certainly the most splendid and palatial structure erected in recent times for purposes of amusement. It cost three millions of pounds and took twelve years to build. With his great daring, Charles Garnier undertook to give monumental expression to the principle "that the exterior masses should interpret the functions of the internal distribution." The emphasising of the great stage-box, of the domical auditorium, and of the state rooms, halls and stairs give a distinctive character to the whole. This great building is well worthy of study. The better we understand the problem, the more we must admire the solution. The general style is that of the Renaissance of Henry II. not uninfluenced by the Neo-Grec movement. In parts (notably the staircase) it appears overladen with ornament; yet above all is the impress of strength, taste and originality: the decrees of necessity expressed in the language of art.

Under the Empire, also, street architecture greatly improved. Pavilions at the street corners and monumental fountains, such as that of Ste. Michel, lent new dignity to the long vistas. Moreover, the impressive avenues and open spaces were made still more imposing by the solidity and beauty of their lamp-posts, clocks and railings. Sculpture, too, plays an important part on the stage of Parisian architecture. Nowhere is there such an abundance of good carving; nor is it confined to buildings of the first importance. In all the designs we note a noble simplicity of composition, due breadth of surface being contrasted with delicacy of design.

Although during the thirty years existence of the Republic there has been no repetition of the Imperial activity, the record is neither unimportant nor uninteresting. The alterations to the Louvre were continued and completed; and the Hotel-de-Ville, which had been destroyed, was rebuilt. The latter is, indeed, an admirable example both in plan and elevation of the skill of the French in solving a monumental problem. It was required that the new building should resemble the ruined one in its general mass, though it might depart radically from it in its general arrangements. Under these limitations MM. Ballu and Depérthes produced a noble design, and the new hotel is in no degree inferior to the old one. It is the most important and the most successful building erected under the Republic; a worthy memorial to the spirit of the architects and artists of our times.

We must not imagine, however, that it is only in buildings of this kind that French architects show their strength of hand and innate refinement of feeling. Almost every suburban château is a testimonial. In houses, however, the best examples are to be found in or near the city. These are innumerable; and so beautiful in their proportions, so quiet, so reserved in their demeanour, so refined in every detail—as to be worthy of the highest praise and closest study. Many there are in which pilasters, cornices, pediments and arches are used in combinations which have been incessantly repeated since they were first employed in ancient Athens; yet used again with a touch of originality so subtle that, while defying analysis, it turns the whole design into poetry.

It is only here and there that isolated fragments, such as the tower of St. Jacques-de-la-Boucherie, remind us of the great Gothic Paris with its innumerable churches and religious buildings. The modern churches are costly and heavy, generally modelled on the Romanesque of Aquitaine. Even the once influential tide of the Gothic revival has ebbed away; and the fairy-like fabrics of mediæval Paris have mostly succumbed to riots and restoration.

Certainly it is hardly possible for the untravelled Englishman to picture the conditions of existence in the old cities of the Continent. Yearly our cities increase and require more space. But in old cities like Paris the same conditions do not obtain. Straitly enclosed within their girdle of fortifications, they cannot spread themselves over the surrounding country. Unable to expand laterally they must ascend vertically. Hence the high houses, those layers of flats, piled storey upon storey, which give to the Parisian streets their aspect of grandeur.

The middle-classes reside principally in these long lines of lofty apartment houses, which are, internally, by no means luxurious. The great height often renders it difficult to secure adequate light or ventilation. Moreover, there is nowhere for children to play; nowhere to air or dry clothes; nowhere, hardly, to shake a duster. The natural restlessness of a nervous and impulsive people is augmented by the lack of domestic quiet. They cannot become attached to their houses by any ties of interest or affection. Hence it is, in looking through this medium of the people, that we discern the truth of the statement, "Great cities are the graves of great nations."

On entering one of these houses the concièrge is first seen flourishing in her lodge. She has a kitchen and another room with a recess. In this recess is the bed, from which, by means of a mechanical device, she can open the street-door to belated inmates. Above the lower storeys, which are devoted to shops, are the flats; and on reaching these the inherent defects in this residential system are at once apparent. Even in the largest apartments the kitchen is near the reception-and bed-rooms. Usually it looks on to an area, and is inconvenient, small and dark. The kitchen boiler is rare, and hot water rarer still. The water tap with the sink—if the house has water laid on to every floor—is placed in the kitchen itself, which is not conducive to visual or olfactory joy. The sanitation frequently leaves much to be desired; and baths as a home institution do not generally exist. Coal or wood has to be fetched from the cellar, five or six storeys down; and as lifts are rare a small stock has to be kept in the kitchen. Such is a fair presentment of an average apartment house in the city of which Victor Hugo wrote, "The smoke of its chimneys is the ideal of the universe."

Whatever be the quality of its chimney-smoke, the artistic refinement and dignity of many of the long facades can hardly be surpassed. It is by no means easy to say which of the various classes of buildings are most deserving of study. Anyone visiting Paris must select for himself; and if he uses due discrimination, cannot fail to glean some useful facts. For, assuredly, nowhere will the artistic appetite be sharper whetted than in the keen intellectual atmosphere of the great art centre.

Rightly the symbol of the city is a ship. For ever upon the deck of Paris one seems to hear the straining, of the spreading unseen sails of human progress.

---

* A paper read before the Bristol Society of Architects.

Masters and Men.

The Midland Iron and Steel Wages Board held a meeting at Birmingham last week. The accountants under the sliding scale arrangement reported that they had examined the returns of sales of iron made by the twelve selected firms for the months of November and December and had verified them with the books. The average net selling price was £6 19s. 5·30d. per ton, which will cause the rate of wage to remain unchanged till April.

The Building Trade.—At the annual meeting of the National Federation of Building Trade Employers held in London last week the question was discussed of making an effort to fix the date for the simultaneous termination of all notices with reference to working rules with the operatives, and it was resolved to take the opinion of the federated employers throughout the country upon this point. Questions relating to the adoption of a new form of contract and closer relationship with kindred national associations upon all matters affecting the general interests of the building trade were also under discussion. Mr. B. I. Greenwood (London) was elected president of the federation for the ensuing year.

Bricks and Mortar.

APHORISM FOR THE WEEK.

When a man understands the art of seeing, he can trace the spirit of an age and the features of a king even in the knocker on a door.—VICTOR HUGO.

Our Plates. WE illustrate three from the large number of drawings in colour by Mr. Edward H. Bennett which gained for him the Owen Jones Studentship Prize in this year's competition held by the Royal Institute of British Architects. Of the delicacy of colouring in the originals our reproductions hardly give a hint. This studentship will allow him to further his studies of structural colour, which unfortunately is so seldom given heed to in modern architecture.—The design for a public swimming-bath for men in a seaside town by Mr. T. A. Moodie won for him a medal of merit in the competition for the Soane Medallion and £100.

Decay of Glasgow Municipal Buildings. REPAIRS are being carried out on the Municipal Buildings on account of decay having set in extensively in the stonework. The matter appears to be serious. The stone of which the City Chambers were built came from the Bannockburn quarries, considered to be the best in the country, but we understand that the particular quarries from which the stone was taken were newly opened. As a precautionary measure, it was stipulated that the material should lie for a year in the builders' yard for the very purpose of testing its durability. The puzzling thing is that, although it seems to have stood the test, the Municipal Buildings have decayed faster than any other building of a similar character in Glasgow. Reference has been made to the deleterious action of the Glasgow atmosphere, but the fact remains that within a stone's throw of the City Chambers there are far older buildings still in a good state of preservation. A report on the decay has been furnished by Mr. Alexander Muir, of Alexander Muir & Sons, who are the contractors for the repairs at present in progress. It was at one time proposed to cut out whole capitals of pilasters, but on the recommendation of Mr. Muir it has been decided to have the decayed portions cut away and a silicate solution applied for purposes of preservation. In this way £600 has already been spent on the east facade of the buildings alone—that is, facing John Street. It seems that stonework exposed to the east and north is more liable to decay than that to the south and west.

St. Augustine's Chair. A GREAT deal of interest has been aroused in the ancient chair or settle said to have been used by St. Augustine, which is now claimed from the committee of the Canterbury Royal Museum by the Bishop of Hereford on behalf of the vicar and parishioners of Stanford Bishop. The chair is composed entirely of oak, and is devoid of nails or other metalwork, and is declared to be a typical specimen of the work of the carpenter in the first six centuries of Roman rule in Europe, corresponding, indeed, in style and construction with a Roman *solium*, or chair of authority. It is oblong in figure; the outside measurement gives 32in. for breadth and 22in. from front to back, and it is deep-backed, with closed sides or ancons to support the arms. There are evidences, too, that it formerly possessed a board upon which to rest the feet. The seat is an oblong slab of oak 26in. in length by 18in. in depth, originally 2in. thick, and still bearing marks of the tool used in smoothing it. The peculiarity of the seat is that it is movable, like the lid of a box, and the cardines on which it is moved are two round tenons left projecting fron the edges, near the back, and inserted into rounc mortice holes in the rear post. In a monograpl written by the late Mr. James Johnston, M.B Lond., on the subject he endeavoured to shov that an early British church existed at Stanforc Bishop, and that the chair was used by Augustin when attending the celebrated synod of Britisl Christian bishops.

Discoveries in Persia. THE collections brought bacl by M. de Morgan from Persi are to be exhibited in the Granc Palais, Paris, in May and June. The Shah wa so pleased with his visit to France that he mad an offer to M. Delcassé to sign a conventio giving France a monopoly of all the archæological treasures found in the south of hi empire, together with half those found in th north. This he signed on the very day he lef Paris. M. de Morgan, M. Maspero's predecesso in Egypt, was consequently sent out at the hea of a mission. Establishing himself at Susa, h engaged from 600 to 1,200 natives at 50 centime a day, the Shah furnishing military protection An enormous number of epigraphic document have thus been brought to light revealing th names of sovereigns up to 3000 B.C., and stil older antiquities are expected to be found at greater depth. One of the chief discoveries is stone, 2 mètres high, the *stele* of King Naramsin 3000 B.C. There is also the obelisk of Kin Manicthon Irba, being the title-deed of estate in Chaldea, and giving in its 12,500 character the whole geography of that country. There i likewise a splendid bronze table supported b four figures and decorated with serpents, as als a bronze column, 4 mètres high, covered wit inscriptions of the eighteenth century B.C. M de Morgan is assisted in his explorations b Père Scheil, who first deciphered the Elamit language.

Enquiries Answered.

The services of a large staff of experts are at the disposal of readers who require information on architectural, constructional or legal matters. Questions should in all cases be addressed to the Editor. The querist's name and address must always be given, not necessarily for publication.

Dilapidated Walls between Gardens.

NEWCASTLE-UNDER-LYME.—F. S. writes: A. is the owner of a house with a long garden; nd she is also the owner of the wall separating er garden from that of her neighbour B. The all is much decayed, slopes over B.'s property a distance of 16½in. out of its vertical, and akes a considerable portion of B.'s garden osolutely dangerous for fear of the wall falling. . has served A. with two notices requesting her remove the danger, but A. pays no attention the notices. What is the best procedure for to adopt?"

You can sue B. for allowing the nuisance to ntinue, and probably obtain damages. This, owever, cannot make her remove it, but if she ntinues it you can keep on claiming damages. ou can also remove the nuisance yourself without constituting a trespass, provided you do not nnecessarily interfere with anything. If there a "Dangerous Structures" department of the l authority you should inform the surveyor, o would take steps to remove the danger and uld probably charge B. with the expense.

Liability for Broken Glass.

CARDIFF.—H. W. H. writes: "Z., a shopter, is requested by a customer X. to remove ent glass stall-plate from X.'s shop front for e purpose of re-lettering and gilding it. Z. t his man to do so, and the glass was taken out d brought back to the workshop. In placing glass upon the bench it broke, apparently by son of a flaw or small crack which had not n noticed when the glass was taken out. Is liable to replace the glass with new at his own t, or must X. bear the cost? No contract l been entered into."

Repairs are done at the owner's risk unless re is an agreement to the contrary. In this e Z. is clearly not liable and X. must bear cost.

Agreement not to Practise.

RADFORD.—SEAL writes: "Referring to the y in your issue for December 25th with rd to an agreement not to practise, supposing agreement were signed at a date during an agement as assistant, and contained the owing clause, 'and not to practise on our own ount at any time hereafter without written sent of employer'—would this clause affect ruling of an agreement as not binding in as stated in the reply referred to?"

he clause is a most reprehensible one, and ld not be binding. Every man is a free t, and none of his rights can be taken away pt by legal contract in which value passes.

Fonthill Abbey.

UTHPORT.—F. H. C. writes: "What is the nt condition of Fonthill Abbey?"

do not know Fonthill, but I gather from ay's "Wiltshire" that the great Palladian e and its successor the pseudo-abbey have disappeared, leaving nothing but an odd nent or so, in the shape of a hermit's cave o forth.

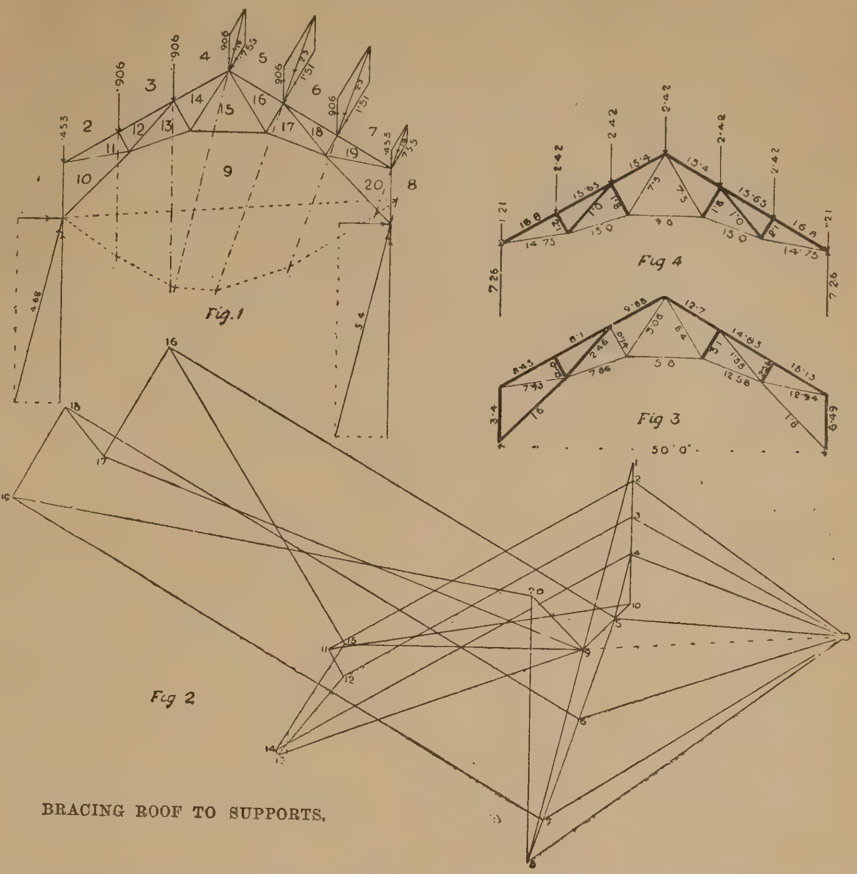
J. A. GOTCH.

Bracing Roof to Supports.

SCARD.—ENQUIRER writes: "Is it desirable t to introduce an angle tie as shown by d line on sketch (not reproduced) at foot rincipal? The structure is of galvanized nd the principals rest on rolled steel joists as stanchions. The roof is in an exposed on facing the sea."

he roof trusses are made exactly according tch they are very unsightly and would be ved by bracing to stanchions, but this would throw an additional stress upon them for which they were not designed. If the stanchions could be braced at the bottom the trusses would not be affected. Fig. 1 shows the frame diagram of roof truss with the suggested braces to stanchions. Fig. 2 the corresponding stress diagram, the trusses being assumed to be 10ft. apart and loaded all over with 21lbs. per ft. super. structural load, and on one side only with 35lbs. per ft. super. normal to surface for the wind-pressure. Fig. 3 shows the stresses in tons on the different members under these conditions, and of course if the wind blows from the other side the stresses will be reversed. Compression is shown by thick lines and tension by thin lines. Fig. 4 shows the original truss without the proposed bracing, and the stresses are those due to a vertical loading of ½ cwt. per ft. super. to cover all contingencies.

HENRY ADAMS.



BRACING ROOF TO SUPPORTS.

Vertical Tiling.

NEWPORT, MON.—A. L. R. writes: "Please give specification of necessary labours and full details showing the best method of finishing vertical tiling hung on fir laths 1in. by 2in., (1) at the eaves, (2) in gable, (3) under window sill. (4) How should a projecting casement frame be fixed to a brick wall? (5) Should the vertical joints between the frame and tiles be made water-tight; if so, which is the cheapest and most effective way? (6) Can you name any book showing details of half-timber construction?"

We cannot spare space in these columns to instruct you in the business of specification writing, &c., but you will find full information in "Specification, No. 5." Vertical tiling is usually hung on fir laths 1½in. by 1½in. Tiles 10½in. by 6½in. by ½in. are usually laid to gauges of 3in., 3½in. or 4in., or, in other words, a lap of 4½in., 3½in., or 2½in. Battens, however, are not the best things to use for vertical tiling, as they harbour vermin, and are sure to decay in time. If the tiles are nailed to the brickwork direct, the gauge is regulated by the thickness of the brickwork, being 3in. or 3¼in., or 4½in. if the bricks are laid on edge, giving a lap of only 1½in., which is not enough. It is therefore better to lay the bricks flat as usual with 1in. thick mortar joints, so as to make the gauge 4in. Another and better method is to nail the tiles to special-made breeze-concrete blocks measuring 1½in. by 9in. by 5⅛in., which jut out beyond the face of the wall so as to allow the nibs of the tiles to rest on them. These fixing blocks are used as stretchers, and you can easily work out for yourself the method of bonding the bricks in a 9in. wall. The nails should be copper or made of an alloy of copper and zinc; galvanized nails are considered by some persons to be best, but this is doubtful, being liable to corrode in time by galvanic action. (1) Fig. 1 shows the method of finishing at the eaves. If the eaves well overhang, as they should do, there is no need to finish the top course of tiles carefully; it is best, however, to push them into cement before nailing, as shown. (2) The same method is employed in the gables. (3) Fig. 2 shows the method of finishing under window sill by means of a strip of lead to keep out wet. This method is preferable to using cement, as the latter would show a somewhat objectionable finish. (4) If you will explain exactly what you mean by a "projecting" casement frame we will endeavour to answer your question. (5) There is no great necessity to make them water-tight, but the best method is to render with cement about 1in. thick and push the nibs of the tiles into it and then nail them. (6) Mitchell's "Advanced Building Construction" gives a few details. In our illustrations plain tiles nailed to battens are shown, but the methods of fixing are exactly similar in all cases.

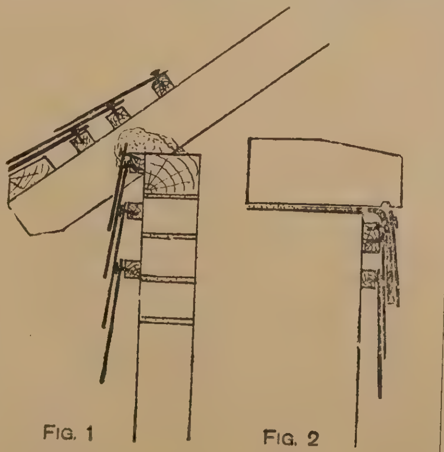


FIG. 1 FIG. 2

VERTICAL TILING.

Correspondence.

Army Works Reform.

To the Editor of THE BUILDERS' JOURNAL.

SIR,—The list of failures chronicled by "Balbus" may be amplified from past press notices.

Aden.—Quarters No. 19 R.A. Lines were twice condemned and vacated by troops, and subsequently turned into married quarters. The roof then falling in, floors admitting scorpions, rats, &c.; cesspools under windows, no ventilation—families preferred for the greater part of year to sleep outside on the sand.

Aldershot.—A refuse-destructor was erected at a cost of £3,000, and never used. Refuse is now removed under contract at a cost of £500 per annum. The lowest tender to work the destructor was £1,500.—Water supply is delivered by gravitation from neighbouring reservoirs. Pumping engines were erected; why, no one knows! The gasworks were abandoned and gasometers filled by the Aldershot Gas Company.—Surgeon-Major-General Patterson declined to occupy the P.M.O.'s quarters, deeming them unfit for habitation.— Zinc scandal: contractor's foreman was sentenced to eighteen months' hard labour, and the N.C.O. R.E. levanted.

Benares.—A new barracks was recently erected in a cantonment notorious for enteric fever.

Bermuda.—Stores scandal: military foreman of works was sentenced to six months' hard labour, subsequently reduced to three months on the ground of negligent supervision of the division officer. Meanwhile the office containing documentary evidence was burnt to the ground—on the second outburst, which occurred within a week of the first.—Works scandal: £6,000 unaccounted for; last news—officer under arrest pending enquiry.

Chatham.—Works scandal: contractor was sentenced to twelve months' hard labour and N.C.O. R.E. committed suicide.

Curragh.—Newbridge: 21st Lancers on arrival from the Soudan in 1900 were housed in dilapidated huts, twenty-eight men in sixteen-men rooms. Both cooking and hospital accommodation were insufficient.—Headquarters block: during Lord Roberts' occupation the drains had to be opened up and were found falling the wrong way.

Devizes.—A broad irrigation system of drainage existed, and a pure absorption one was substituted in a subsoil of stiff clay. Two months later the latter blocked up and the sewage forced its way to the surface into a ditch beyond, within 150yds. of the married quarters. The local authorities intervened.

Devonport.—An epidemic of diphtheria occurred and troops were removed. £10,000 were spent in remodelling drainage.—A vast sum of money was spent on land forts now lying derelict.—A slipway for mining launches was laid years ago and never used as the entrance through the boundary wall at the gun wharf was too narrow to admit boats of this type.

Dover.—An excess of £15,000 occurred in a battery owing to mistake in setting out.—The military prison, originally designed for convicts by Sir E. Du Cane, R.E., is surrounded by a wall consisting of external skins of half-brick encasing a filling of chalk. The rain filtered in, the chalk swelled, and a long length of wall fell down; it is now made good with concrete, but the rest is crumbling away.

Dublin.—The barracks are hotbeds of enteric fever. Five boards were summoned in one set of garrison orders to enquire into cases in five separate barracks. The late Duke of Clarence contracted fever in Marlborough Barracks, then recently erected. Cerebro-spinal-meningitis, due to very insanitary surroundings, is rife amongst children.—Lord Salisbury said, at the annual dinner of the Institution of Civil Engineers in 1895, in the presence of the then Inspector-General of Fortifications: "I hope some day the Civil Engineers, for the military engineers will not do it, will remove the reproach of typhoid fever from our barracks."

Edinburgh.—Piershill Barracks are bounded on the north by a cesspool; the married quarters are hovels; sanitary arrangements are exceedingly imperfect; the barrack-yard is riddled with sewer-pipes, and bounded on east and west by open sewers.

Gibraltar.—Four Spanish workmen were killed a year ago by the collapse of a magazine roof; the centering had been struck within fifteen hours of the completion of the work. Verdict of coroner's jury—error of judgment on part of Royal Engineers responsible.—Two more Spaniards were killed by the explosion of a mine at the Station Hospital a few months afterwards. The verdict was not published in this case. The old hospital was a disgrace to civilisation, and exposed to shell fire.

Kumasi.—Two Royal Engineer officers designed a fort a few years ago which was washed away by the first rains and is now replaced by a more substantial structure.

London.—Hounslow Barracks: the district council forced the War Office to remodel the drainage at a cost of £10,000. All troops, including hospital patients, had to turn out. The lower drainage was also set right after much bungling.—The South Kensington Museum sapper fire brigade was not long ago dispensed with, as it was more of a danger than a safeguard to the valuable collection concerned.

Longmoor.—The huts recently erected in a swamp are now condemned. £30,000 will be required for purchase of a new site, and this, with the removal of huts, will run into six figures.

Lucknow.—An epidemic of cholera occurred in barracks, which was due to a contaminated filter-bed.

Malta.—Pembroke Camp: the sanitation was so bad that troops had to turn out under canvas on to the parade ground during winter-time. Tents were blown away, bedding damped and kits damaged.

Portland.—No water was available in barracks for ablution purposes, and drinking water had to be carted three miles.

Rangoon.—The forts sank, became useless, and guns were removed, leaving the port practically defenceless.

St. Helena.—A site for new barracks was acquired at a cost of over £2,000 which had exchanged hands a few years before for £80. Typhoid fever raged. The walls of a new infantry barracks appeared a few inches above the ground, and the scheme was abandoned. Subsequently the walls of a gymnasium and married quarters block were carried up to the eaves, and also abandoned. A military prison is now being erected.—The married quarter R.G.A. are unfit for habitation, and men 6ft high find it difficult to move about in them. Troops who were under canvas from February to September last waited for tent bottoms, though timber and sappers abounded.

Salisbury.—The manœuvres of 1898 had to be partially abandoned at the last hour, as the engineers had not considered the water-supply. Portable steam engines were requisitioned to force water through hose to various sites. The price paid for ground acquired was 25 per cent. too high, *e.g.*, a proprietor was offered £600 which was refused, and matter referred to arbitration, with result that he was awarded £480. Taxpayers lost £20,000 over this deal!

Shorncliffe.—The new huts are failures, and cannot be kept warm; the old ones are preferable in this respect. The walls of a large span building not long erected were lately under repair, and had to be cross-tied to prevent collapse.

South Africa.—Portable huts were designed by civilians at Cape Town for troops at the front, and sent up to sappers for erection; the latter failed, and civilian tradesmen had to follow for the purpose. Certain firms were not allowed to tender for the supply of corrugated iron for these huts, yet the firm accepted was permitted to sub-contract with them for this material!

Windsor.—The barrack drainage was chaotic, with four types of unventilated drains meandering over the place and impossible to trace. The officers' mess became dangerous to live in. The Secretary of State for War when questioned, replied, "Other barracks are in a worse state and Windsor must wait its turn."

Woolwich.—Cambridge barracks: families of eight had to inhabit single rooms 16ft. by 13ft. 3in. by 10ft. Accommodation at Warley and Oxford was equally bad.

Surrey.—A correspondent lately wailed in press columns: "As at present doled out we shall have to wait some twelve years for the revised 1in., over forty years for the revised 6in., and 300 odd years for the new parish map." Many Ordnance sheets are forty years behindhand, so much so that whole tracts of country cannot be recognised on them. Stations, docks, &c., in existence for years are not yet entered. The other day a statement appeared in the press to the effect that the Royal Engineers were to be sent to the colonies to prepare military surveys for defensive purposes. Why did they not occupy themselves in this respect in the past? Had they done so, Buller would have been spared his humiliation at Colenso and possibly his subsequent disgrace.—Yours truly,

ARCANA.

Builders' Notes.

The Leyland Master Builders' Association held its annual meeting last week. The following officers were appointed: Mr. James Tomlinson, president; Mr. C. E. Marland, secretary; Mr. J. Tomlinson, junr., treasurer; Mr. F. Rose and Mr. T. Knowles, auditors.

Mr. G. F. Daniel, of Argyle Street, Swansea, has been chosen for the post of assistant building inspector at Salford out of 160 applicants. Mr. Daniel was teacher of the building department at the Swansea Intermediate and Technical School for two years, and is qualified by the Sanitary Institute to act as sanitary inspector.

The Newcastle-on-Tyne, Gateshead and District Master Plumbers' Association held its annual general meeting last week, when the following officers were elected: President, Mr. R. W. Cooke; vice-president, Mr. J. G. Walker; hon. treasurer, Mr. J. T. Corking; hon. secretary, Mr. George Robson; and hon. auditors, Messrs. J. Stewart and S. Percy.

London County Council.—At last week's meeting of the Council, in the report of the General Purposes Committee a letter was presented which had been received from Mr. W. Adams, resigning his post as manager of the Works Department. Mr. Adams said the post, under existing conditions, involved so much anxiety that he felt a continuance of the position could only result in the breakdown of his health. The resignation was accepted.—The Council approved estimates of £68,000 and £576,350 for the reconstruction for electrical traction of further portions of the Council's tramways on the south side of the Thames.

Two Fire Tests with Jarrah and Karri Floor and Doors were conducted last Wednesday at the testing-station of the British Fire Prevention Committee. The floor consisted of 10in. by 10in. beams over which 2½in. planks were laid and loaded with bricks exerting a pressure of 200lb. to the sq. ft. The test lasted two hours, the floor withstanding the flames remarkably well. The next test was with two doors 2in. thick, one made of well-seasoned Jarrah wood, the other of Karri wood comparatively new. After fifty minutes (during which time the temperature rose about 2,000 degs. Fahr.) the Karri door gave way, collapsing after another ten minutes; while in the case of the Jarrah door towards the close of the test (of one hour's duration) the flames just passed through in one small place. This also was considered highly satisfactory. Full particulars will be given in due course in the Committee's publications.

The Nottingham Master Builders' Association held its annual dinner last week. The chair was occupied by the president Mr. H. Vickers, and the vice-chair by the vice-president, Mr. F. H. Fish. Mr. James Wright proposed "The Mayor, Magistrates and Corporation," and the Mayor, Councillor E. N. Elborne, J.P., replied. Councillor J. Wright submitted the toast of "The Architects." Mr. A. W. Brewill, in response, said he was often sorry that they could not go back to the old times when the architect was the master-builder, and when he loved his work. Large buildings had to be rushed nowadays and it took a great deal of pleasure from the work. He sincerely wished that they had some system whereby all contracts were remunerative, the contractors receiving a fair price without running the risk of losing money through strikes and other unforeseen circumstances. He thought there had been a great improvement in the architecture of the buildings in the city during the last few years.

IDEAL PLUMBING.—I.

By G. A. ALLAN, Plumbing Instructor, Trades Training School.

IN this connection the word "ideal" is used strictly in its dictionary sense, namely, "reaching an imaginary model or standard of perfection." "Plumbing" is used as the Americans use the word, to include drains and hot-water supply. "Ideal plumbing" is such as one would carry out where perfection in plumbing was desired and expense was a minor consideration.

It by no means necessarily follows that because plumbing is expensive, therefore it is good. In one of the largest hotels in London the execution of the plumbing and drainage work is as near perfection as such work can be. But there are many tons of lead pipe and many hundredweights of plumber's solder and of brass in that hotel that the plumbing would have been much more sanitary without. Though the execution of the work was good, the design was faulty.

In reconstructing the sanitary arragements of a nobleman's house in London, a well-known firm laid three parallel drains from the rear to the front of the building. One drain was for sewage, one for rainwater and one for waste water. This was worse than wasting money; it was making an insanitary job; for one pipe would have been better than three, as it would have carried off all the drainage, and would have been three times as well flushed with one-third the liability to leak or get out of order.

Whether or not any thing, scheme or system is ideal is, ultimately, a matter of opinion. All English writers on plumbing and sanitation advocate the use of lead as the best possible material of which to make soil pipes, and they are equally unanimous in condemning iron as an unsuitable material. In America lead soil pipes are condemned as insanitary and unsafe, and cast-iron is considered an ideal material of which to make them. The Model By-laws issued by the Local Government Board recommend that all waste pipes discharge over a channel leading to a trapped gulley at least 18in. distant. In America waste pipes are connected with the soil pipe or drain in the same manner as water-closet apparatus. The by-laws of the London County Council forbid the construction of water-closet apartments so that the door shall open into any room used for the purpose of human habitation. In America it is not unusual to find a water-closet apparatus fixed in a recess in a bedroom, and only curtained off from the rest of the room.

In a recently-published book an English writer "at the risk of becoming wearisome" (to use his own words) repeats for the fifth time the necessity of disconnection from the drain of all waste pipes. Such a writer would not see a sanitary job of plumbing in the whole of the United States.

An ideal system of plumbing would provide water, hot or cold, at any place where it was required, quietly and effectively, and would remove foul water and waste matters in the same manner. Such a system would be practically silent and quite inodorous. All pipes would be absolutely sound. All drains and soil and waste pipes would have sufficient fall to cause the matters discharged into them to be carried off rapidly, and they would be continually traversed by currents of fresh air, which would carry off any noxious gases that might be formed in them. Plumbing fixtures must empty rapidly, and must be of the best shapes for their several purposes. All traps must be self-cleansing, and no foul water must remain on the premises after it has served the purpose for which it was used.

In reconstructing the drains of a building already erected it is necessary to ascertain the depth of the sewer below the level of the inlet to the drain furthest from the sewer, and the distance of such inlet from the sewer. The depth divided by the distance will give the available fall. If the difference of level be 3ft. and the distance 120ft., then $3 \div 120 = 1 \div 40 = \frac{1}{40}$, or 1 in 40. In making a drainage plan it is also necessary to be sure that the drain so arranged for will be deep enough to allow for the connection of fixtures between the sewer and the furthest inlet. If the available fall is less than 1 in 40, provision should be made for periodically flushing the drain.

The gradient at which drains should be laid is variously stated. It is often asserted that—

1 in 40 for a 4in. drain,
1 in 60 „ 6in. „
1 in 90 „ 9in. „

and so on, are suitable falls, and that this "decimal rule," as it is called, is easily remembered.

Like many statements containing a modicum of truth, this table is often misleading. It really means that where there is a sufficient flow of sewage to cause a 4in. pipe to run half full, a fall of 1 in 40 is sufficient. Similarly, when the quantity of sewage will keep a 6in. or 9in. pipe running half full then a fall of 1 in 60 or 1 in 90 is appropriate.

But I have heard this rule quoted by a man who wished to lay a 9in. pipe because the available fall was only 1 in 90, though the sewage was not more than a 4in. pipe would easily pass. In this case a 4in. pipe would be better than a 9in. pipe, because, even with a fall of 1 in 90, the 4in. pipe, by concentrating the flow, would keep cleaner.

A fall of 1 in 40 should be secured, if possible, throughout the whole drainage system. When houses or other buildings are designed this should be the fall calculated on. It is rather a reflection on an architect to design and superintend the erection of a building and then to request the sanitary authority to lower their sewer as the cellar is too deep to be drained!

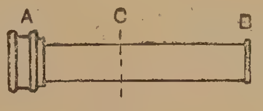

FIG. 1

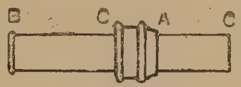

FIG. 2

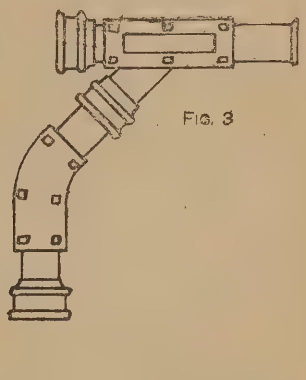

FIG. 3

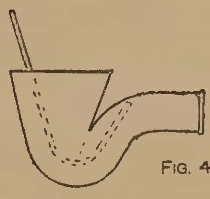

FIG. 4

When designing new buildings the fall of the drains is usually a matter under the control of the architect; but when reconstructing the drains of a building already erected the depth of the lowest floor, like the depth of the sewer, is already decided; and the best must be made of circumstances as they are found.

Until recently, vitrified stoneware pipes jointed with Portland cement were considered the best materials of which to construct drains; and when they are laid properly in straight lines, with true inverts, sound joints, and cleaned off inside, on thick concrete beds of proper width and covered with 6in. of good concrete, there is no doubt that they form a good drain. But cast-iron has now displaced stoneware as the material for drain pipes on all best work.

The very best material of which to form drains is undoubtedly heavy cast-iron glass-lined pipes of the same substance as used for water mains. They are stronger than stoneware, and therefore less liable to fracture, and the number of joints (and therefore chances of leakage) is very much reduced. They are jointed with gaskin and molten lead in the same manner as water mains in the street, and can therefore be laid to resist a much greater pressure than it will be possible to submit them to in practice. One very large mansion in London in which the available fall for the drain was very small was re-drained with glass-lined cast-iron pipes, a flushing cistern was fixed at the head of the drain, and the work gave every satisfaction. These pipes can be obtained in any length up to 12ft. by so ordering them, but as waiting for some exact length might cause delay it is necessary occasionally to cut them. Fearing the effect of the cutting on the glass lining, also the heat of the molten lead, and of the jarring caused by caulking the joint, I had a 3ft. length of 6in. pipe cut and jointed as shown in Figs. 1 and 2. The pipe A B was cut at C and the part C B was caulked into A, the cut end being inserted into the socket. The inside of the pipe at the joint could be seen and felt quite easily, and the glass-lining was quite unaffected, although the end inserted had been first cut and then had had the joint made round it. Of course the pipe must not be cut with hammer and chisel, but with ordinary pipe-cutters in the usual way.

The stock of fittings for such drains is so large and varied that no trouble is found in running the drain in any direction at any angle. All bends and junction-pieces should be fitted with inspection openings and movable doors; by this means the inside of the drain can be inspected from end to end. By holding a lighted candle at one opening and a small mirror at an angle at the next opening, the reflection of the inside of the drain can be seen without trouble. The outsides of the pipes are treated with Dr. Angus Smith's or similar solution.

Where the drains pass under the walls (and this applies to all drains), an arch should be turned over them at a distance of about 6in., or the wall over the opening should be supported by a stone or iron support.

In detached and semi-detached houses no drains should be laid under the building. In terrace-houses, and in houses built as in streets, it is generally necessary to lay the drain under the house from back to front. It is not always done, however. Lately, in a new house, on the drainage of which I was asked to report, I found the water-closets, bath and scullery sink all fixed against the front wall. The only drain under the house was one for surface-water, and it was disconnected by discharging through a side inlet into a gulley in the front area.

When the drain is laid under a house there should be no opening to it except in the open air. The only openings to the drain are those for ventilation and for connecting soil pipes, waste pipes from slop sinks and urinals, and grease-traps and gulleys. It would simplify matters if the waste pipes from slop sinks and urinals were called soil pipes. They must be of the same material and mode of construction as soil pipes, and I shall therefore include them under that head.

The soil pipes, gulleys and grease-traps should be in the open air, and where they are so fixed no opening to the drain is necessary inside or under the building. The drain should be laid on a bed of concrete at least 6in. thick and projecting beyond the pipe on each side to a distance at least equal to the external diameter of the pipe. The concrete should be made of good Portland cement 1 part and clean gravel 6 parts, or 1 of cement, 2 of sand, and 4 of broken brick or stone. Burnt clay should not be used, nor any substance too large to pass through a 2in. ring.

Right-angled junctions should never be used. When one drain joins another at an angle of 90 degs. a 45-deg. branch fitting and a 45-deg. bend should be used, both fittings having inspection doors (see Fig. 3). The covers to all inspection doors should be well bedded in red-lead putty (made by mixing dry red lead with white lead in oil) and hemp, and should be bolted down with gunmetal bolts or set-screws. Care must be taken that each time they are removed and replaced the drains are again subjected to the water test

In designing the sanitary system for a building it should be remembered that the fewer the fixtures the more sanitary the work. One water-closet used twelve times is much better than twelve water-closets used once. As many fixtures as are necessary for the convenience of the inmates should be provided, but no more. The number of gulleys should also be reduced to a minimum, and each gulley should do as much duty as can be arranged for. Gulleys fixed for draining off the surface-water should be provided with side inlets and rainwater and waste pipes connected to them. If possible. no gulley should be fixed either for surface-water or for rain-water which does not also receive the water from a waste pipe. In a period of drought, when drains are most foul for want of being flushed, and when the hot weather makes sewer gases more dangerous, surface and rain-water gulleys are liable to become unsealed by the evaporation of their contents. For this reason it is sometimes better, even when two waste pipes lead through the wall together, to have them discharging into different gulleys and so ensure the seal of both. Surface-water gulleys which do not receive the discharge of a waste pipe should have a very deep seal, not less than 6in.; it may with advantage be 1ft. As the gulley does not receive foul water, there is not the same necessity for it to be self-cleansing; and as it contains such a large body of water it will be less often unsealed by evaporation. If the gulleys receive, as they should, special and regular attention, those having deep seals will be as easily attended to as the self-cleansing variety.

THE SOUTHWARK END OF LONDON BRIDGE, 1831 ("LONDON AFTERNOONS").

The controversy over the question of intercepting traps between the main drain of a building and the sewer has been settled in London by the County Council issuing a set of by-laws which makes their use compulsory. Most places had already adopted the same attitude, which is supported by all English, and some American, writers.

The reason for using a trap on the main drain is to cut off the drain completely from the sewer, so that no sewer gas and no infectious matter passed into the sewer from other buildings shall gain access to the house drain. Thus the only noxious gases in the drain will be such as have been generated in the drain itself; and with properly laid and well-flushed drains this will be reduced to a minimum.

The objections to intercepting traps are that with properly laid, properly trapped (at the gulleys and fixtures), sound and well-ventilated drains they are unnecessary, as any bad gases in the drains escape above the roof. That the flow of sewage is checked by the trap, that the trap always contains a quantity of more or less foul matter, and that when the pressure in the sewers is suddenly increased the air and gases are forced through the traps into the house drains—are objections. The objectors point out that at one time it was the practice to disconnect soil pipes from drains and branch drains from the main drain, as well as the latter from the sewer; that for purposes of disconnection traps with two or three seals were invented; and that these traps are now useless. They expect the drain-intercepting trap to follow the soil-pipe disconnectors. It is pointed out that one great benefit derived from omitting the interceptor is that the sewers are all ventilated by the drain ventilators.

Drains intercepted from the sewer are freer from danger than when not intercepted, provided always that the drain between the sewer and the intercepting trap is ventilated. If this section of drain is unventilated, the sudden filling of the sewers, as by a storm, forces the traps: the sudden subsidence of the flow in the sewers draws air through the traps into the sewers, which may leave the traps unsealed. If the air in the sewer is particularly foul it passes through the water in the trap, being absorbed on the sewer side and given off on the house side of the trap.

Having laid the drain of cast-iron glass-lined pipe, at a fall of or exceeding 1 in 40, on a bed of concrete at least 6in. thick, with an intercepting trap near the boundary of the premises drained, with two openings for ventilation near the interceptor, one on each side, and one opening for ventilation at or near the highest part of the drain, and one opening at the further end of every long branch drain, it is necessary to test the drain for soundness.

The usual test is to close the lower end of the drain and to fill it with water. If the water subsides there is a leakage which must be found and stopped. If the water does not lose head the outside of the joints should still be examined for "sweating," *i.e.*, a slight leakage too small to show at the higher end for a long time. Before filling the drain a small piece of compo pipe should be passed through the gulleys to allow the escape of air that would otherwise be confined in the crown of their traps (Fig. 4).

In America the work of the plumber in a house is divided into "roughing in" and "finishing." The former process consists of fixing the drain and soil, waste and ventilation pipes—all the work which is covered up in process of building. Before it is covered up it is tested, either by being filled to the top of the soil pipe with water, or by having both ends stopped—generally with plaster-of-Paris—and air pumped in until the pressure-gauge registers 5lbs. or 10lbs. to the sq. in. The latter is the more satisfactory as well as the more severe test. It can be applied to the largest system or the highest building without having an excessive pressure anywhere, as happens when a long vertical pipe is filled with water. The pressure is great enough to find all the weak places without being so great as to burst anything. It is easily applied, and leaks are readily found either by sound or, when too small for that, by going over the joints with soapy water, when the escaping air will blow soap bubbles, and so indicate the position of the leak.

Views & Reviews.

Old London.*

It is not probable that our descendants will look back on the London of to-day in the same way as we regard the London of four or five centuries ago: though one might even hazard the reflection that machine work will become so universal in the future that even those of our own productions which are now considered to be unsatisfactory may come to be regarded with the admiration attaching to a work of art. Romance always tends to associate itself with the past and rarely with the present; it often makes things appear different to what they really were, and this is the reason why people frequently adopt the attitude of unrestrained admiration in regard to the buildings, handiwork or domestic articles of the Middle Ages; not that they are wrong in doing so, but such a sentimental judgment is neither true to the past nor to the present, and it needs to be watched ere it run rife.

Doubtless it is the comparison with things as they are to-day which makes the London of the Middle Ages so fascinating: the changes since those bygone days are so strange and so completely overwhelming. Mr. Loftie, for example, takes his readers for a walk through the London of five centuries ago. Most people then lived in the City proper, and merchants did not resort to it only for business purposes and retire to villas in the suburbs, for few except the monks and the day-labourers dared to live beyond the protection of the city walls, which commenced at the Tower (so admirably and comprehensively dealt with in Lord Gower's book).

Outside Aldgate there was a hamlet called Whitechapel and near it a house of Sisters who were popularly known as Minoresses (hence Minories). Shoreditch was the estate of an honourable family named Shore; while Finsbury probably denotes the residence of Fin, maybe a Dutch settler like his neighbour Hacon, who is commemorated in Hacon's ey, or Hackney. Cripplegate had nothing to do with cripples but with a covered way, or Crepulgeat; and Ludgate had no associations with King Lud, but recalled a lidgate or postern. However, let us pass through this latter gate and on to the small bridge over the Fleet. There are pleasant orchards of the Bishop of Ely (Ely Place) on the right; and if we pass along where Fleet Street now is we shall see the house of the White Friars on the left, then, further up, the great monastery of the Knights Templars, and further west again Temple Bar: beyond which is open country with a road (now the Strand) winding through it, a mere muddy track overgrown with bushes and skirted on the right by gardens and thickets. On the left, between the road and the river, are some half-fortified town houses of the bishops, Exeter House being the most important; while below them are walks along the Thames like those now seen at

"The Tower of London," Vol. 1 (in two volumes), by Lord Ronald Sutherland Gower, F.S.A. London: George Bell & Sons, York Street, Covent Garden, price 21s. nett.

"The Portfolio: Mediæval London," by Canon Benham, D.D., F.S.A., and Charles Welch, F.S.A. (with numerous collotype reproductions of old drawings). London: Seeley & Co., Ltd., 38, Great Russell Street, price 5s. nett.

Richmond. Further afield we see the magnificent palace of the Archbishops of York (afterwards known as Whitehall and its gardens as Spring Gardens), the aviary or mews for the King's hawks (where now stands the Nelson Column), the Convent of Westminster, the church of St. Giles-in-the-Fields, and so to the Oxford Road, near the pleasant village of Holborn.

And thus one proceeds among parts which are now so altered. It would occupy too much space to deal with a tithe of the matter which Mr. Loftie presents in such an interesting and authoritative manner; of his description of old St. Paul's with its wooden spire 150ft. higher than Wren's ball and cross; of the City companies and the guilds; of the older City churches; of the present St. Paul's; and of the London of a century ago. There is, however, one concluding remark which should be made in reference to the accompanying illustration of Alfred Stevens's monument to Wellington (which, with those of old London Bridge and old Westminster Bridge, we are enabled to reproduce through the courtesy of Messrs. Cassell & Co.). Alfred Stevens was undoubtedly the greatest sculptor we have yet produced; yet this great work of his was most wretchedly dealt with. It had been designed for the easternmost arch on the north side of the cathedral, but before it was removed to its present position ten years ago (through the exertions of the late Lord Leighton and some friends) the Dean and Chapter had actually allowed it to remain for about twenty years behind the oaken screen in the consistorial church and against the light of a south window; and even now it is incomplete, as the top is without the equestrian statue which Stevens designed for it.

WESTMINSTER BRIDGE, HALL AND ABBEY 100 YEARS AGO ("LONDON AFTERNOONS").

ALFRED STEVENS'S MODEL OF THE WELLINGTON MONUMENT ("LONDON AFTERNOONS").

Fletcher's History of Architecture.

The fourth edition of this work is undoubtedly superior to the former ones, having been almost rewritten by the junior author. In the process it has been considerably enlarged and the price unfortunately increased. This is regrettable from the fact that a book is needed for the younger students, craftsmen, and for all interested in building, and such a price as twenty-one shillings does not appeal to those to whom it is most likely to be of use. From the demand which Fletcher's "History" has met with, the need of a good book can be appreciated. This present edition is illustrated by a very large number of half-tone blocks, by no means so good as the collotype prints of previous editions, but remarkably good of their kind and well suited to their purpose; and we are compelled to the conclusion that the chief value of the book lies in these illustrations. Mr. Banister F. Fletcher has improved the book considerably by basing his analysis of the styles mainly upon construction, from which the forms spring.

In considering the work we must bear in mind what are the aims of a history of architecture. First and foremost we undoubtedly require the facts. Then these should be co-ordinated in order to show their due relation to the result, and as the view of their relation depends upon a true perception of their importance, and furthermore as we need to judge the scale or value of these results, the principles laid down by the author must be true, as they will colour his theories throughout. The older histories were chiefly concerned in the collection of facts, and are invaluable in this respect. Viollet-le-Duc did somewhat as Darwin did in collecting abundant evidence upon particular species, drawing conclusions from them sufficient to give a workable theory, which has been enlarged by patient workers bringing fresh facts to be judged by the evolutionary theory and from an enlargement of view due to the development of science in general. For some time architectural historians were busy collecting facts with some little and incomplete attempts at co-ordinating them. Of recent years we have been improving in this respect, several very able contributions to the history of particular epochs having been made by various writers; but there is a want of a critical essay summarizing the facts that have been collected and arranging them in orderly evolution. Mr. Banister F. Fletcher accepts the evolutionary theory, which no one qualified to judge now doubts, as may be judged from statements throughout the book and the very plan of the work, *i.e.*, the comparative method. Unfortunately his use of the "comparative method" is so mechanical that the due relation of the detailed facts is lost by separation under various headings, which make each division appear of equal value. This fault would have been somewhat retrieved if the general introduction had been more complete and wide in its grasp—an essay in itself—and if afterwards at the end of each chapter there had been a somewhat similar summarizing. At present the want of grasp makes the book of little real value as an incentive to and basis for further study, or, what is of greater moment, to give a student the true principles of architecture, educating him to better our future architecture. The adoption of divisional headings has led to a great deal of useless verbiage where there was a want of material. The language too is often high flown and not as simple as the subject warrants. Fine writing we can pardon in such as Ruskin, where it serves a legitimate purpose and is thoughtful, but where introduced only for the sake of effect it blurs a clear perception.

The book does not contain enough details of construction to show the reason of the architectural forms. The details of ornament, on the other hand, although none too many, are out of proportion to their legitimate place. These illustrations are lettered in the style familiar in students' competitions, making the wording hard and wearisome to disentangle and destructive of clearness in the thing represented.

In reference to what we are pleased to call the "Classic" and "Gothic," we have the usual statement that the one is of the "beam" order and the other of the "arch," and that the pointed arch is the keynote of the latter, a statement that appears excellent to a student at first sight, but is really beside the mark. Of course such views are elaborated with glib statements as to "Gothic" being the "intense expression of its age" and "the keen artistic refinement of the Greeks," such as students use in examination papers without apprehending their true meaning. The chapter on Prehistoric Architecture which has been added is most meagre, although it afforded an excellent chance of introducing the beginnings and then working on to the more complex forms of later civilizations. In the Egyptian chapter the general questions of the influence of geography, geology, climate, &c., on architecture are first dealt with instead of in the introduction, as should be. The accounts of the religions of various countries are generally wrong, that of Egypt in particular. This chapter and that of Assyria are very weak, and many of the facts stated are incorrect. We are glad to see that a section has been added on the "non-historical" styles of India, China, Japan and Central America, this term being unfortunately used to signify that they exercised little direct influence on other styles, but Mr. Fletcher little apprehends the intimacy that came from the great trade routes between Europe and further Asia, and the influence of India and China on Assyria was considerable and through the latter affected Greece, as we know. The finest timber architecture in the world—that of Japan—is very meagrely dealt with. It is to be regretted that no good detailed account of this has been published, as it would be of inestimable benefit to modern construction.

One very important element in a history has been generally omitted in describing the examples of each style, namely, the particular uses of the buildings, for only from an apprehension of these can a student understand the reason of a building having its particular form. This is as necessary as the other functions dealt with by which the architectural form is determined. The book needs considerable revision before it can be relied upon for its facts; and, as we have said, its conclusions will give a student a very imperfect notion of the evolution of architecture.

"A History of Architecture on the Comparative Method for the Student, Craftsmen and Amateur." By the late Prof. Banister Fletcher, F.R.I.B.A., and Banister F. Fletcher, A.R.I.B.A. Fourth Edition, revised and enlarged. London: B. T. Batsford, 94, High Holborn, W.C.; price 21s. nett.

R. I. B. A.

ADDRESS TO STUDENTS.

BY JOHN SLATER, B.A.

A MEETING of the Royal Institute of British Architects was held last Monday evening. Mr. John Slater, vice-president, was in the chair. Mr. W. J. Locke, secretary, announced the decease of Mr. W. G. Penty, F.R.I.B.A. Mr. Slater then announced that the Council had decided to submit as a fit recipient of the Royal Gold Medal for this year the name of Mr. J. F. Bentley, architect of the Roman Catholic Cathedral at Westminster, for his work as an architect.

The following were then elected members:—As *Fellows*, Messrs. John Parker (Cape Town), Andrew N. Prentice (London), John Robert Moore-Smith (London) and F. Henry Tulloch (Belfast). As *Associates*, Messrs. Charles Thomas Adshead (Liverpool), Sidney Walter Bensted (London), Ernest George Besant (Cambridge), Austin Barugh Botterill (London), Charles Alfred Broadhead (Nottingham), Dean John Brundrit (Ulverston) Harold Busbridge (London), Ralph Scott Cockrill (Great Yarmouth), William John Devlin (London), Walter Ernest Dobson (London), James Ewing (London), Edward Lawrence Gaunt (Bradford), Arthur Everett Gibbins (London), Francis Robert Boyd Haward (London), Ralph Eustace Hemingway (Nottingham), Augustus Edward Hughes (London), Allen Trevis Hussell (Ilfracombe), Ernest William Lees (London), Edward Berks Norris (Birmingham), Leonard Rycroft Oakes (London), Harold Frederic Pondon (London), Cyril Edward Power (London), William Beddoe Rees (Cardiff), Charles Herbert Reilly (London), Ernest George Rodway (Bristol), Andrew Sharp (Montreal), George Lister Thornton Sharp (London), William Slater (Nottingham), Francis Danby Smith (London), Walter Stephen Tucker (Newmarket), Arthur Halcrow Verstage (Godalming), Edwin Paul Wheeler (London), Joseph Alfred Woore (Derby) and Edmund Livingstone Wratten (Croydon).

Mr. John Slater then read an address to students in which he said:—The architectural student of to-day, if he takes an intelligent interest in the history of his art, must be much impressed and somewhat puzzled to notice how very fluctuating and short-lived have been the various fashions of architectural taste during the last hundred years or so. If he looks to ancient times, when the world was young and what Lord Leighton calls "the spirit of spontaneous, unquestioning joy in production" was paramount, this was not the case. The styles of architecture which the early building peoples evolved for themselves to suit the vicissitudes of climate, the varying necessities of their public and private life, the nature of the building materials found in the country, and various other local conditions, persisted with slight variations for centuries, and only died with the decay of the nations themselves. Since the renaissance of classic taste all has been changed.

In 1827 was published a work illustrating the recent buildings erected in Regent Street and on the outskirts of Regent's Park, and speaking in terms of no unstinted praise of the excellence of the designs. Yet in 1836, when the Houses of Parliament were in course of erection, we find the Gothic style to the fore. In 1867 every one of the competitive designs for the new Law Courts was in the Gothic style. A generation later what do we find? You are all acquainted with the storm which was raised a few weeks ago anent the Liverpool Cathedral competition, and I need not quote the opinion of a distinguished modern architect as to the competency of the Gothic style to meet the requirements of to-day! Now I think it very probable that all this may lead an architectural student to exclaim: "A plague on both your houses! Why should I bother my head with learning anything about Classic or Gothic, Romanesque or Renaissance? All art is ephemeral; utilitarianism is the only guide. These styles are now all dead, and will give me no help towards designing a town-hall, an infirmary or a modern residence." Now I do not think it can be too strongly impressed on those who may be disposed to hold such views that they will be utterly wrong if they take this line. What is it that stirs the emotion even of the unlettered man when he gazes down a vista of columns, gigantic and awe-inspiring, in an old Egyptian temple, or looks upon the perfect grace of the Parthenon or the stupendous relics of mighty Rome, or when in some old mediæval cathedral he looks up to the springing arches and intricate ribbed vaulting, but the feeling that, different as may be the forms which present themselves, there is such fitness in the purposes of each and in the connections of all the parts with each other, such perfection in the combination of form and colour, that the nett result in every case is beauty. The buildings which have attracted and which will attract the most universal admiration are not those at the sight of which we exclaim "How enormous" or "How wonderfully clever," but those which are beautiful. I am old-fashioned enough to think that an architect ought to try to make his building beautiful, and that a protest should be made against what appears to me to be the cult of ugliness which has been growing of late years. There is too great a tendency nowadays to mere eccentricity and originality among the younger men. There have been several buildings erected lately the cleverness—I had almost said the infernal cleverness—of which cannot be denied for one moment; but are they beautiful? There is far too much straining after effect, too great eagerness to achieve something not attempted, or at any rate not achieved, before; and, as has been well said, "when the achievement becomes obvious, is it not by way of becoming uninteresting?" I am not arguing in favour of a dead level of monotony which is uninteresting, even if the level be a high one; I have no love for the stereotyped style of art which the Continental methods of education and study too often result in. If a man be a true artist his individual emotions, the bent of his mind, all the idiosyncrasies of his character, are bound to come out in his work; but do not let your main idea and aim be to display your idiosyncrasies.

A real genius may be original because he has the knowledge and the power to work out his original ideas; but what can be more contemptible than to see the weak, jejune and spiritless attempts to copy what may be admired as an original work of genius, while the copy only shows the lack of genius in its exponent? Your buildings are the vernacular in which you have to express the architectural ideas which are in you, and, depend upon it, the simpler and more direct that language is, the more eloquently will it appeal to the world. Be assured, therefore, that the time you may spend in studying old work will never be wasted; such study will fit you better to soar into the heights which science is opening out. And, further, the study of old work will teach you another most important lesson—never to lose sight of the nature of the material in which you are working. In the best old work the material is never tortured; one form of ornamentation and enrichment is suitable for stone, another for brick, and another for wood; and this has always been lost sight of when art became debased, with a result that a mere *tour de force* is attained from which, however much we may admire the skill which produced it, we turn with relief to the simpler, truer and more legitimate methods of treatment.

Let me urge you to cultivate an easy, terse and direct literary style. When you get into practice you will have to write reports and to carry on daily correspondence on all sorts of subjects, and you should endeavour always to make your own meaning as clear as possible to those you are addressing. It often occurs to me how lamentably deficient in literary style are the majority of architects' letters.

The field of an architect's practice is ever widening, and in fact it is now so extensive as almost to deter men from entering on it. All the new discoveries of science, which at first are simply laboratory experiments, are gradually made to subserve our daily needs and requirements, and as soon as this has taken place our clients expect us to advise them with reference to all new inventions, and you will find it to your great advantage to keep *au courant* with the times by noting and, if possible, investigating the utility of new inventions affecting architecture. But the powers of any individual are limited, and I feel sure that the near future will see a good deal of devolution of the manifold duties undertaken by architects. And I see no reason why this should turn out to the detriment of the architect. On the art side he can be associated with the sculptor, the painter and the mosaic worker, and on the scientific side why not with the engineer? Quite recently this Institute urged the desirability of associating an architect with an engineer in bridge design, and I am confident it would often be desirable to associate a professional civil engineer with an architect in the case of large buildings where difficult problems of support or construction have to be considered, the best arrangement of electric wiring, and so forth. The very wideness of the field covered by an architect's practice, with all its manifold responsibilities, has, however, its compensations. As your practice increases you need never be haunted by the dread of monotony. Your work will probably take you afield into various parts of the country, and every fresh building which you have to design will present new difficulties as to site, aspect and accommodation, &c., which it is a never-ending pleasure to try to overcome. Architecture is so many-faceted and touches so many planes of modern life—ecclesiastical, municipal, commercial and social—that an architect ought above all other men to be broad-minded and to avoid anything like cliqueism or a haughty bearing towards his fellows. Remember that, however fascinating and lofty may be your designs, the effect of your buildings when finished depends not upon yourself but upon the builder who carries out your designs, the foreman who looks after the work, and even the individual carpenter who fits a moulding or the labourer who mixes the concrete.

Mr. Henry T. Hare then criticized the designs and drawings submitted for the prizes and studentships. He thought the high level of previous years had been well maintained and that some of the work was in advance. The prizes were then presented by the chairman.

A vote of thanks, proposed by Sir Alma Tadema R.A., and seconded by Mr. John James Burnet, president of the Glasgow Institute of Architects, was accorded Mr. Slater and Mr. Hare.

Keystones.

The Year-Book of the Society of Architects has just been issued.

Mr. J. F. Bentley, architect of the new Roman Catholic Cathedral at Westminster, entered upon his sixty-third year last Thursday.

Mr. Henry Hugh Dyer, architect and surveyor, of Northampton, died recently in his seventy-second year. He erected a great number of churches and chapels in the neighbourhood.

A Monument at Dakar is to be erected in honour of the traveller and explorer, Paul Blanchet. It takes the form of a stela of granite bearing a medallion portrait by M. Henri Dubois.

The Competition for a Monument to Bismarck has been decided, and the prize of 10,000 marks awarded to Hugo Lederer, an Austrian sculptor, pupil of Professor Schilling, of Berlin. The other three prizes went to Munich, Charlottenburg and Berlin. The monument of the "Iron Chancellor" will be erected at Hamburg.

Kingston-on-Thames Public Library Competition.—Mr. Maurice B. Adams, Mr. E. Milner Allen, Messrs. Carter and Ashworth, Mr. J. A. Cox, Mr. A. J. Hardwick, Messrs. Hennell and Sons, Mr. S. B. Russell and Mr. Sidney R. J. Smith have been invited to submit designs in this limited competition. Mr. Basil Champneys is the assessor.

A Church Hall and Cloisters at Liverpool have been erected as a memorial to the Rev. John Brunner and Sir Henry Tate by Sir John Brunner and Mr. Henry Tate, to complete the scheme of buildings of Ullet Road Unitarian Church. The architects were Messrs. Thomas Worthington and Percy Scott Worthington, of Manchester. A fresco painting has been executed by Mr. Gerald Moira, professor at the South Kensington School of Art.

A Chancel Screen of carved oak has been erected in the Church of St. Matthias, Earl's Court, in memory of the late vicar, the Rev. J. P. F. Davidson. It is unusually lofty and open, and every effort has been made to preserve an uninterrupted view of the sanctuary and east window. The central arch is surmounted by a rood. The chancel of St. Matthias, which was erected some years before the nave, was separated from the latter by a low stone wall and gates, which remain, and it was always understood that the architect's original conception provided for a lofty screen.

Three Towns Architects' Annual Dinner.—The annual dinner of the Plymouth, Devon and Stonehouse branch of the Devon and Exeter Architectural Society was recently held at Plymouth. The chairman, Mr. Charles King, F.R.I.B.A., in proposing the toast of "The Royal Institute of British Architects and Kindred Societies," said that while they all looked up to the Royal Institute as an ancient and honoured institution, he heartily wished and hoped that it would become less conservative than it had been in the past, and that it would awake and show a little more life and interest in the work which it had to do. If the whole of the provinces would unite and make a strong appeal to and demand upon the Institute, perhaps it would awake and rise to a new effort in aid of architecture.

Finsbury Circus Garden.—This latest addition to the open spaces of the City has been opened to the public. The Metropolitan Drinking Fountain and Cattle Association have given two drinking fountains. A plain granite one has already been fixed, while on the side near to the London Institution a fountain built of open-timber work in English oak, and covered with a conical roof of ornamental red tiles surmounted by a bronze finial, is to be erected. In plan it is circular, having six divisions, three of which are entrances, the remaining sides being filled in with timber struts and cement rough-cast. The whole is raised on two grey granite steps. The actual drinking fountain is circular, and is to be of polished red granite and placed in the centre. There are three lion-head water jets, one opposite each of the entrances. The width is 6ft. 6in., and the total height 17ft. Both have been designed and made by Messrs. John Whitehead & Sons, Ltd., of 74, Rochester Row, Westminster.

Selby Abbey Church Tower is considered to be unsafe and steps are to be taken for its reparation.

Spillman Court, a historic mansion near Stroud, Gloucestershire, was completely destroyed by fire last week. For some years past the place had been unoccupied. Among the things destroyed with the building are a number of handsome oak mantelpieces and artistic panellings.

A Stained-Glass Figure of Queen Victoria has been placed in the west window of Oswaldkirk Church by the villagers, as a memorial of Her late Majesty. It is the work of Messrs. Burlison & Grylls, executed under the direction of Mr. Hodgson Fowler, F.S.A.

New Public Offices at Felling are being erected on Sunderland Road. They will be entirely of stone, the walls being faced with coursed rock-faced blocks, and the dressings will be moulded and polished. The style is Italian Renaissance. The cost of the building without the site will be about £7,000. The contractor is Mr. John Wilkinson, and the architect Mr. H. Miller, A.M.I.C.E., both of Felling.

A New Council House and Public Offices at Sparkhill, for the Yardley Rural District Council, have been opened at a cost of, including site and equipment, £16,000. The building is in modern Renaissance style, with the introduction of a slight Tudor feeling, and it is of brick, with stone dressings, stone mullion windows, stone cornices, and Cotswold stone tiled roof. Mr. A. Harrison is the architect, and Mr. W. Bishop the builder.

A New Wesleyan Chapel at Osmaston-by-Derby has been erected in Gothic style. The total seating capacity is about 433 adults or a mixed congregation of 560 persons. The walls are of brick, with Derbyshire stone dressings. The total cost of the building including the cost of the land, architect's fees, &c., is about £3,000 The architect is Mr. John Wills, F.S.Sc., of Derby and London; and Mr. William Edwards, of Derby, is the builder.

Books dealing with Capitals.—Referring to the enquiry which appeared recently in our columns, a correspondent points out that although there is no book dealing solely with capitals, the following works contain much information about them and many illustrations of various important examples:—"Matériaux et Documents D'Architecture et de Sculpture," by A. Raguenet (André, Daly Fils & Cie, publishers, Paris); "Le Musée de Sculpture Comparée du Palais du Trocadéro," 2 vols. (published by Armand Guérinet, editeur des Musées Nationaux, Paris); "Examples of English Mediæval Foliage," James Kellaway Tolling, F.R.I.B.A. (published by B. T. Batsford, 1874); "Art Foliage for Sculpture and Decoration," by the same author (published by himself in London, 1865); "The Churches of the Nene Valley, Northamptonshire," by E. Sharpe, J. Johnson and A. E. Kersey (B. T. Batsford, 1880); "Southwell Cathedral: Principal Capitals and Carvings in the Chapter House" (J. Whittingham, bookseller, Southwell, Notts, price 1s. 1½d. post free).

Stuart's Granolitic Stone Co., forced by their increasing business and the numerous contracts now on hand, have been compelled to remove from their old premises at Limehouse to a much larger manufactory at Glengall Road, Millwall. On Wednesday evening last, by invitation of the managing director, a housewarming party was held in the new premises. The guests (both ladies and gentlemen), about 100 in number, and all wearing rosettes of Stuart tartan, had an excellent dinner served to the strains of the bagpipes. The toast of "The Firm and Staff" was proposed by Mr. William Walter, and responded to by the company's secretary, Mr. Napier Trollope. Mr. P. Stuart, the managing director, also complimented the members of the staff and referred to the lengthy periods of service of most of them. He also proposed the toast of "The Visitors" in one of his characteristic speeches. This was replied to by Mr. Harry Hooper, who in welcoming the company to the district favourably contrasted the Millwall of to-day with the "Isle of Dogs" of a hundred years ago. The chairman's health was proposed by Mr. W. Clarkson, the architect of the new building. An impromptu programme of songs and recitations and a few dances filled up a most enjoyable evening.

Liverpool Cathedral Site.—The Liverpool Cathedral Committee has just issued in pamphlet form a "Statement of the Arguments" in favour of the adopted site, St. James's Mount. These arguments, however, are now threadbare.

The Barrow Master-Builders' Association held its annual dinner last week. Alderman W. Gradwell, the retiring president, occupied the chair, and Mr. W. Ramsay, the president-elect, the vice-chair.

A New Church at Frimley, Surrey, is being erected to take the place of the chapel-of-ease. The west end and nave only are to be erected at present, at a cost of about £2,000. It will accommodate 500 persons.

The New Imperial Hall, Dulwich, has been opened. It is capable of seating 700 persons. Two smaller halls—to be used as smoking and refreshment lounges—are in direct communication with the main hall.

Rodin is making a bust of Victor Hugo which will be reproduced in bronze. The striking mask of the poet in the Panthéon served as model. Destined for the Musée Hugo, there will be placed alongside it a replica of David d'Angers's bust of the author of "Chosen Vues."

At Hoo All Hallows Church, Rochester, during the recent restoration two fine arches—one fourteenth century and the other earlier—have been discovered. A consecration cross in a good state of preservation was also uncovered. The church, which dates from the Norman Conquest, and its ancient early Norman font and fifteenth-century oak pews and chancel screen, have been carefully preserved.

A Draught Preventer has been devised by Mr. Edward A. Harman, M.I.C.E., of Huddersfield, which consists of a roller about 2in. in diameter and of the width of the door; it is attached to the inside by means of a pair of lugs having vertical slots in them, thus allowing the roller to slide freely up and down over any irregularities of the floor. In some cases the roller may be in several pieces, about 3in. long, on an axle.

Mr. Edward Clark, architect of the Capitol at Washington, died recently. Mr. Clark was born in Philadelphia in 1822, and was assistant to Dr. Thomas U. Walter when the latter was engaged in the construction of the wings and dome of the Capitol from his own designs. On Dr. Walter's resignation of his position, in 1865, Mr. Clark succeeded him and has ever since had charge of the building.

Statuary for Blackfriars Bridge.—At last week's meeting of the Court of Common Council it was agreed: "That it be referred to the Bridge House Estates Committee to consider and report on the practicability and cost of completing the original design of Blackfriars Bridge by the erection of suitable statuary on the four pedestals of the bridge in commemoration of the Coronation of His Majesty the King."

The Clerk of Works Association of Great Britain held its nineteenth annual dinner at the Holborn Restaurant on Monday evening last. There were over 200 present, and the chair was occupied by Mr. Aston Webb, F.R.I.B.A. Mr. John Davies, M.C.W.A., in a short speech proposed "The Architects and Surveyors," which was responded to by Messrs. Edwin T. Hall, F.R.I.B.A., C. F. Selby, F.S.I., and James Bartlett, M.S.A. Mr. John Aitchison toasted the "Worshipful Company of Carpenters," with which body the Clerk of Works Association have long had close connection. This was responded to by the Master of the Company, Mr. John Willson, M.P. The toast of the evening was, however, "The Clerk of Works Association," which was proposed in a telling speech by the chairman, who pointed out what he considered to be flaws in the Association in the question of lack of rules, age-limit, and the non-existence of a benevolent fund. He also emphasised that much could be done by the clerks of works to modify what was spoiling the building trade—the action of unions in trying to restrict the output by making two men do one man's work. The president, Mr. Spencer Green, in reply stated that the Association was now applying for articles of incorporation, and all the chairman's points would be dealt with. Other toasts were duly honoured, and an interesting musical programme filled up the evening.

A Monument to Colonel Villebois Mareuil will be erected in Montaign, Vendée.

The late Mr. F. W. Porter, J.P., F.R.I.B.A., of Moyle Tower, Hythe, who died on November 17th last in his eighty-first year, left an estate of the value of £39,801 14s. 11d.

A New Central Board School for Perth has been opened. It has accommodation for 620 children, and comprises ten classrooms, apart from teachers' rooms, while it is fitted up with the most modern sanitary, heating and electric light arrangements. At the Caledonian Road school a new workshop, cookery-room, laundry and gymnasium have been provided. The total cost of the new school is £12,970, while the cost of the extension at the Caledonian Road school is estimated at about £500.

Surveying and Sanitary Notes.

Treatment of Sewage.—At last week's meeting of the Institution of Civil Engineers Mr. J. Davis, M.I.C.E., read a paper on "The Sewerage Systems of Sydney, N.S.W., and its Suburbs," which, he said, were now nearing completion, having involved an expenditure of £3,300,000. About 400 miles of sewers were in use, serving a population of 290,000; but these figures would be largely increased with the extension of reticulation. The main systems, at a final cost of about £4,000,000, would provide for a prospective population of over 1,000,000. Mr. W. Naylor, A.M.I.C.E., in a second paper dealt with the general experience already obtained in connection with the treatment of domestic sewage containing trades waste. His conclusion was that in only two cases, first, with sewage containing an abundance of trades waste, consisting largely of starch or starchy products, such as that from breweries, distilleries, bleach-works, dye-works, and calico-print works, and secondly, with trades waste charged with free chlorine, was there difficulty of any but a mechanical nature in treating such sewage and waste bacterially. The self-purification of certain samples of manufacturers' waste on standing had suggested the experiment of trying colour-shop waste from calico-print works, brewery-waste, &c., on an active bacterial filter. It had been found that, although a certain amount of disintegration took place, it was accompanied by "souring," and the effluent was unsatisfactory. This "souring" had been found to be prevented by preliminary contact with putrid sewage, or sewage-sludge, which probably resulted in the introduction of more active and competitive ferments than the lactic acid or other acid ferment.

The Sanitary Inspectors' Association held its annual dinner at the Holborn Restaurant last Saturday night. Sir James Crichton-Browne, the president, occupied the chair, and he thought the pressing question with which they had to concern themselves now was that of the housing of the people in town and country. In the solution of that problem sanitary inspectors could give invaluable assistance and help. On behalf of the members he presented to Mr. W. H. Grigg, the late chairman of the council, a diamond ring and an illuminated address in recognition of his services to the association. He looked forward to the time when all health questions in this country and the care of the sick in body and mind would be placed under the control of a separate department of the Government, represented by a Cabinet Minister. Public security would be enhanced, economy and sound administration would be advanced by the creation of a properly equipped ministry of health. He read an extract from a letter which had been received by Mr. Tidman from the hon. solicitor, Mr. Aubrey Richardson, stating that at their last meeting the trustees of the Chadwick Trust on the suggestion of Sir James Crichton-Browne, resolved that a sum of £50 and a Chadwick medal be presented to that member of the Sanitary Inspectors' Association whose official report or reports made in the discharge of his duties during the year 1902 should, in the opinion of the trustees, be judged most conducive to the advancement of municipal or rural sanitation.

New Patents.

These patents are open to opposition until March 8th.

1901.—**Hydraulic Jacks.**—942. J. C. CRELLIN, 40, Park Lane, Liverpool. The device consists of a telescopic hydraulic ram vertically mounted on a wheeled carriage and having a platform at its head. The truck also carries a water-reservoir and a hand pump.

Windows.—2,098. J. THORPE, 79, Westbury Street, Pinfold Lane, Sheffield. The object of this invention is to do away with cords, pulleys and weights. At each side of the window is a box enclosing a coiled spring, to which two slotted segmental arms are pivoted, being connected by a pin which passes through a plate on the bottom rail. By these means the window can be retained in any position.

Soil, Rainwater and other Pipes.—3,272. G. T. ASHTON, 16, Derby Range, Heaton Moor, Stockport. The pipe is plain at one end and has a socket at the other which is divided vertically into two parts held together by nuts and bolts. If a pipe is required to be removed for repairs or other purposes, the top or loose half of the socket is unfastened and a new pipe substituted. The invention also provides for the casting of the top half of the socket on to an otherwise plain pipe, so that both are removed together.

Drying Walls.—18,032. H. SPATZ, 106A, Gitschinerstrasse, Berlin. In order to quickly dry whitewashed and other walls they are coated with a solution of oleic acid, 10lbs., dissolved in benzine 10lbs.

Excavating Apparatus.—20,023. E. H. TAYLOR, 512, Commercial Avenue, Cairo, Illinois, U.S.A. A large auger is arranged within a pipe which is supported vertically and has a hopper at its upper end. At the bottom of the pipe is a horizontal auger driven by power. This cuts away the material, which is then carried by the screw into the hopper, whence it is discharged.

The following specifications were published on Thursday last, and are open to opposition until March 15th. A summary of the more important of them will be given next week.

1901.—301, ROBERTSON & HAMILTON, suspending window sashes. 400, GUSTORF, protecting cover for new buildings. 671, WALLER, partition walls. 677, HASSALL, MELLOR & BROOK, flushing water-closets. 857, BEVIS & HUTCHINGS, instantaneous grip vices. 2,984. DOMAN, brackets for supporting rainwater gutters. 3,119, NICHOLLS & GILL, water or other taps. 3.695, JOHNSTONE, heating of greenhouses, conservatories, &c. 4,164, WILLCOX, portable mortar or concrete-mixing machines. 4,602, FERRY, domestic and other firegrates. 4,630, HITCHINS, asbestos linings for buildings. 4,772, LINTOTT, machinery for making bricks. 5,109, FULCHER, roofing buildings. 5,450 CANCALON, ceilings. 8,206, SPEIGHT, ladders. 10,160, KEEBLE, manufacture of bricks, tiles, &c. 17,073, SMITH, metallic coupling for temporarily connecting chains, ropes, &c. 19.299, RALLINGS, ball valves. 20.821, WELLMAN, sash locks 22,828, ANDERSON, combined brick and tile facings for walls 22,829, ANDERSON, systems of ventilating fireproof buildings. 24,237, POTTER, window-fasteners. 24.486, JUNKE, couplings for wrought-iron pipes. 24,923, BOIVIE, manufacture of artificial stone.

A City Architect wanted for Manchester.—The Town Hall Committee of the Manchester City Council last week considered a report on the reorganisation of the City Surveyor's Department as suggested by the special committee which recently had this subject under consideration. It was stated that the Committee, with the assistance of the City Surveyor, had made a few changes in the internal working of the department, which involved the resignation of one official and one or two new appointments. As a result of this reorganisation it has been decided to recommend the Council to set up an independent City Architect's Department, to take over the architectural work hitherto done in the Surveyor's office. It was also decided to recommend that a City Architect should be advertised for at a salary of £600 a year.

THE SMALL-POX OUTBREAK

should be sufficient to determine all readers around London to adopt No. 3 of

Our Insurance Schemes

while the advantages obtainable by the other two Schemes are obvious, so much so that applications are being constantly received from all parts of the country.

These are the three Schemes:—

(1) *A Free Accident Insurance of* **£500** *to every regular reader of our paper.*

(2) *An Accident Insurance of* **£500,** *and also*
£250 *for Permanent Total Disablement.*
£2 10s. *per week for Temporary Total Disablement.*

Premium, 1/-

(For the conditions under which policies Nos. 1 and 2 are issued readers should refer to our pamphlet, sent on application.)

(3) *An Accident Insurance of* **£1,000,** *with the following special additional advantages:*
£500 *for Permanent Total Disablement.*
£6 *per week for Temporary Total Disablement.*
£1 10s. *per week for Temporary Partial Disablement.*
£30 *Annuity.*
£3 *per week during confinement from such illnesses as Small Pox, Diabetes, Scarlet Fever, Carbuncle, &c., &c.*

Ordinary Risks, Premium, £3/-
Hazardous Risks, Premium, £3/10/-

Write for Proposal Form.

These Insurances are guaranteed by the Ocean Accident and Guarantee Corporation, Limited.

SPECIAL NOTICE.

(1.) It is not necessary to subscribe direct to the office in order to secure the benefits of the above schemes.

(2.) Even if ordered through a newsagent the subscription need not be prepaid for a year. It is sufficient to order it and pay as may be arranged with the newsagent.

(3.) It is sufficient for us to have an intimation from the newsagent that he supplies copies regularly.

(4.) Policies can be issued either direct to the subscriber or through the newsagent, whichever may be preferred.

(5.) In applying it is only necessary to write a postcard, giving the full name and address of the newsagent from whom the copy is obtained.

A Pamphlet, giving full details of the **THREE SCHEMES** will be sent on application to

THE MANAGER, BUILDERS' JOURNAL,
EFFINGHAM HOUSE, ARUNDEL ST.,
STRAND, W.C.

COMPLETE LIST OF CONTRACTS OPEN.

DATE OF DELIVERY.	WORK TO BE EXECUTED.	FOR WHOM.	FROM WHOM FORMS OF TENDERS MAY BE OBTAINED.
	BUILDING:		
Feb. 6	Maesteg—School, Classrooms, &c.	School Board	E. W. Burnett & Son, Architects, Tondu, near Bridgend.
" 6	Drogheda, Ireland—10 Labourers' Cottages, &c.	Meath Rural District Council	P. Dowdall, Clerk, Council Office, Workhouse, Drogheda.
" 6	Cardiff—Engine House, &c., at Pumping Station	Corporation	C. H. Priestley, Waterworks Engineer, Town Hall, Cardiff.
" 6	Radcliffe, Lancs—Octagonal Brick Chimney	Urban District Council	W. L. Rothwell, Engineer, Council Offices, Radcliffe.
" 6	Retford—Church	——	T. Glen, junr., Accountant, Union Street, Retford.
Feb. 6	Great Lever, Bolton—Cotton Mill	Beehive Spinning Co., Ltd.	Potts, Son & Hennings, 79 St. George's Road, Bolton.
" 6	Tooting, S W.—Covered Ways at Workhouse	Union Guardians	C. A. Sharpe, 11 Old Queen Street, Queen Anne's Gate, S.W.
" 7	Stockingfield—Engine Shed, Offices, Tank House, &c.	Midland Railway Co.	Company's Architect, Cavendish House, Derby.
" 7	Aberaman, Wales—2 Blocks of 12 Houses and 1 Villa	——	G. A. Treharne, 18 Canon Street, Aberdare.
" 7	Bowness—Additions, &c., to Hotel and Villas	R. Rigg	S. Shaw, Architect, Kendal.
" 7	Leicester—Public Baths	Baths Committee	A. H. Hind, 3 Grey Friars, Leicester.
" 7	Shooters' Hill, Greenwich—2 Brick Vaults at Cemetery	Greenwich Borough Council	Rating and Adoptive Acts Department, Royal Hill, Greenwich.
" 7	Sheffield—Shops, Offices, &c.	Corporation	Gibbs & Flockton, 15 St. James's Row, Sheffield.
" 7	Treorky, Wales—18 Houses	——	M. Falcon, 33 Bute Street, Treorky.
" 7	Blenau Gwent, Wales—Rebuilding Chapel	Primitive Methodists	A. Jones, Rosebery Street, Abertillery.
" 7	Crumlin, Mon—House	——	R. L. Roberts, Architect, Abercarn.
" 7	Kirkcaldy—Carpenter's and Plasterer's Work to Tramcar Depôt.	Corporation	W. L. Macindoe, Town Clerk, Kirkcaldy.
" 8	Leeds—Police Station and Free Library	Watch Committee	W. H. Thorp, 61 Albion Street, Leeds.
" 8	Londonderry—Residence	W. N. M'Guiness	J. P. M'Grath, 28 Carlisle Road, Londonderry.
" 8	Shrewsbury—Headquarters Police Offices	Standing Joint Committee	A. T. Davis, County Surveyor, Shire Hall, Shrewsbury.
" 8	Belfast—Fireclay Goods, Cement, Slates, &c.	Belfast & Northern Counties Rlwy. Co.	Mr. Ellis, Stores Superintendent, York Road Station, Belfast.
" 8	Ballymena, Ireland—Medical Officer's Residence, &c.	Union Guardians	C. Johnston, Clerk, Workhouse, Ballymena.
" 8	Donegal—Bathroom and Water-Closets	Union Guardians	D. C. Pearson, Clerk, Workhouse, Donegal.
" 10	Falkirk—Poorhouse	Parish Council	A. & W. Black, Architects, Falkirk.
" 10	Port Talbot, Wales—Business Premises	W. Bowers	G. P. Davies, Architect, Port Talbot.
" 10	Bilston, Staffs—Car Shed and Offices, &c.	Wolverhampton Electric Tramways, Ltd.	Secretary, Donnington House, Norfolk Street, Strand, W.C.
" 10	Coventry—5 Cottages and Buildings at Sewage Pumping Station.	Corporation	J. E. Swindlehurst, City Engineer, St. Mary's Hall, Coventry.
" 10	London, S.W.—Cement, Lime, Bricks, &c.	Wandsworth Borough Council	H. G. Hills, Town Clerk, Council House, Wandsworth, S.W.
" 10	Eastbourne—Technical Institute, Library, Science and Art Schools, Fire Station, &c.	Corporation	Borough Engineer, Town Hall, Eastbourne.
" 10	Griffithstown, Wales—Re-erecting Bridge	Panteg Urban District Council	D. J. Lougher, Engineer, Pontypool.
" 10	Stockton—Church	Baptist Connection	T. W. T. Richardson, 57 High Street, Stockton.
" 10	Cardiff—Extensions of Kitchens, Larders, &c.	Infirmary Guardians	E. Seward, Architect, Cardiff.

Like the KOH-I-NOOR pencils the finest ever produced and will be appreciated by every Architect and Draughtsman.

Unquestioned Supremacy amongst Pencils is held by the KOH-I-NOOR.

L. & C. Hardtmuth's KOH-I-NOOR Pencils give the most entire satisfaction. The name Hardtmuth is a guarantee of excellence. The pencils do what is expected of them—sharpen to a fine point, do not snap off, and prove the most economical in use. The quality never varies. Made in 17 degrees, for all purposes!

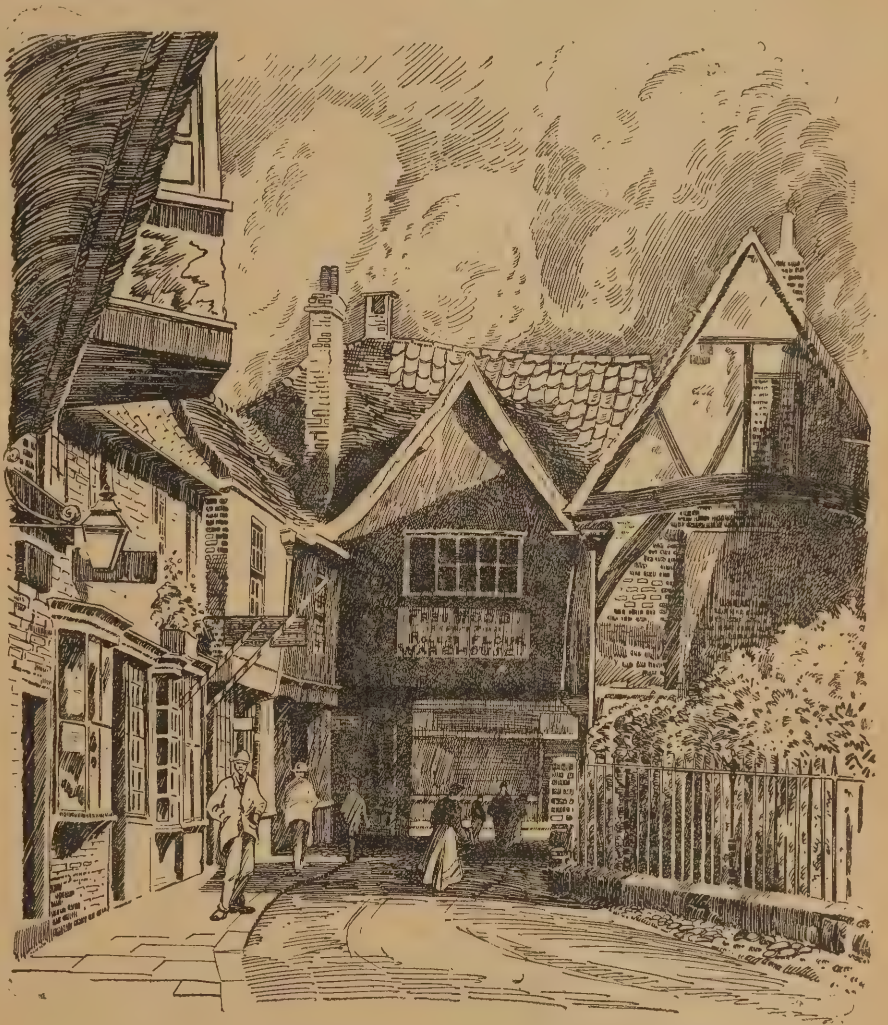
An Architectural Causerie.

Slums after Slums. SOME persons consider that for corporations to clear away slum areas and erect model dwellings on them is merely wasting the ratepayers' money and causing new districts to be made disreputable. This is a familiar view of the case, but it is certainly astonishing to find the Manchester Corporation demolishing slum dwellings at Miles Platting and replacing them with forty jerry-built houses which are said to be almost as unfit for people to live in as the hovels which formerly covered the site. The Town Hall Committee was appointed to enquire into the matter and the result of their investigation is that they call for the resignation of the chief architectural assistant in the City Surveyor's Department. There is sad blundering here, and it does not improve the Manchester Corporation's reputation. It is however significant that the Town Hall Committee recommend that the architectural and the surveying departments of the Corporation shall be separated. We have on more than one occasion deprecated the economy which puts too much responsibility on one man, necessitating his superintendence and direction of so many things at one time, yet at Manchester it seems that this has been the policy freely adopted. As long as the work is done somehow or other, nothing becomes known publicly of the troubles, and it is only when mishaps occur that the folly of this municipal parsimony is seen: and then follows a hullabaloo and recriminations, the officials and not the system being blamed.

The Danger to York Minster. IT is difficult to find valid reasons for the ruthless destruction, or attempted destruction, of valuable and highly picturesque buildings which has occurred again and again in York. The latest example of this spirit was the attempt made to remove the old gateway in College Street, shown in the accompanying drawing. According to a general custom the cathedral close at York was surrounded with walls and entrance was gained by means of four gateways. Of these the threatened gateway in College Street is the only one remaining. Having been treated most severely in the past and still more so during recent years, it now presents a very patched-up appearance. Perhaps it possesses no special architectural merit, but it is certainly picturesque and groups very charmingly with the fifteenth-century college of Saint William hard by. The Corporation, however, who seem incapable of realising that York's great and only distinction is its possession of invaluable antiquities, decided to pull the gateway down to relieve the congestion of traffic in Goodramgate. The result of this proposal would have been a great increase of traffic round the Minster, and especially so towards the eastern portions. Strong representations were made by the Dean and Mr. Bodley, R.A. (the consulting architect to the Chapter), and many others, pointing out that the vibration caused by the great increase of traffic would seriously imperil the safety of the Minster and particularly the east front, which already shows several very ominous cracks. The Corporation, however, were obdurate and actually commenced pulling down the half-timbered cottages to the south of the gateway, preparatory to the removal of the archway itself. At this juncture Mr. Frank Green, a patron of art who takes great interest in local relics, offered to make good the sums already expended on the purchase of the building and to restore it to something like its old beauty, provided the Corporation would promise to devise some alternative route for the new street. This, one is glad to say, has been done, and the new street will be made a little to the south, thus saving the archway and keeping the traffic away from the eastern front of the Minster. But even with this concession the proposal cannot but be regarded as most unfortunate. It is a bad policy at the best to disturb the serenity of a cathedral close with the noise of heavy traffic; it is still more so when that traffic endangers the stability of a structure so universally famous as that at York. Even now, according to a statement by the clerk of works, a passing cart causes a vibration which can be felt to the topmost pinnacle of the south transept, and it must not be forgotten the upper portions of that transept are several feet out of the perpendicular. Although the fragile eastern front, with its huge window, will be avoided by the new route, the same cannot be said for the south transept, for there the traffic will pass close to the base of the porch steps. A great chorus of indignation and protest has been raised, but so far in vain. We can only hope that even yet the municipal authorities will reconsider their proposals and do nothing in any way to jeopardise the safety of a building which is not merely of local but national importance.



OLD GATEWAY IN COLLEGE STREET, YORK. DRAWN BY W. AINSLER.

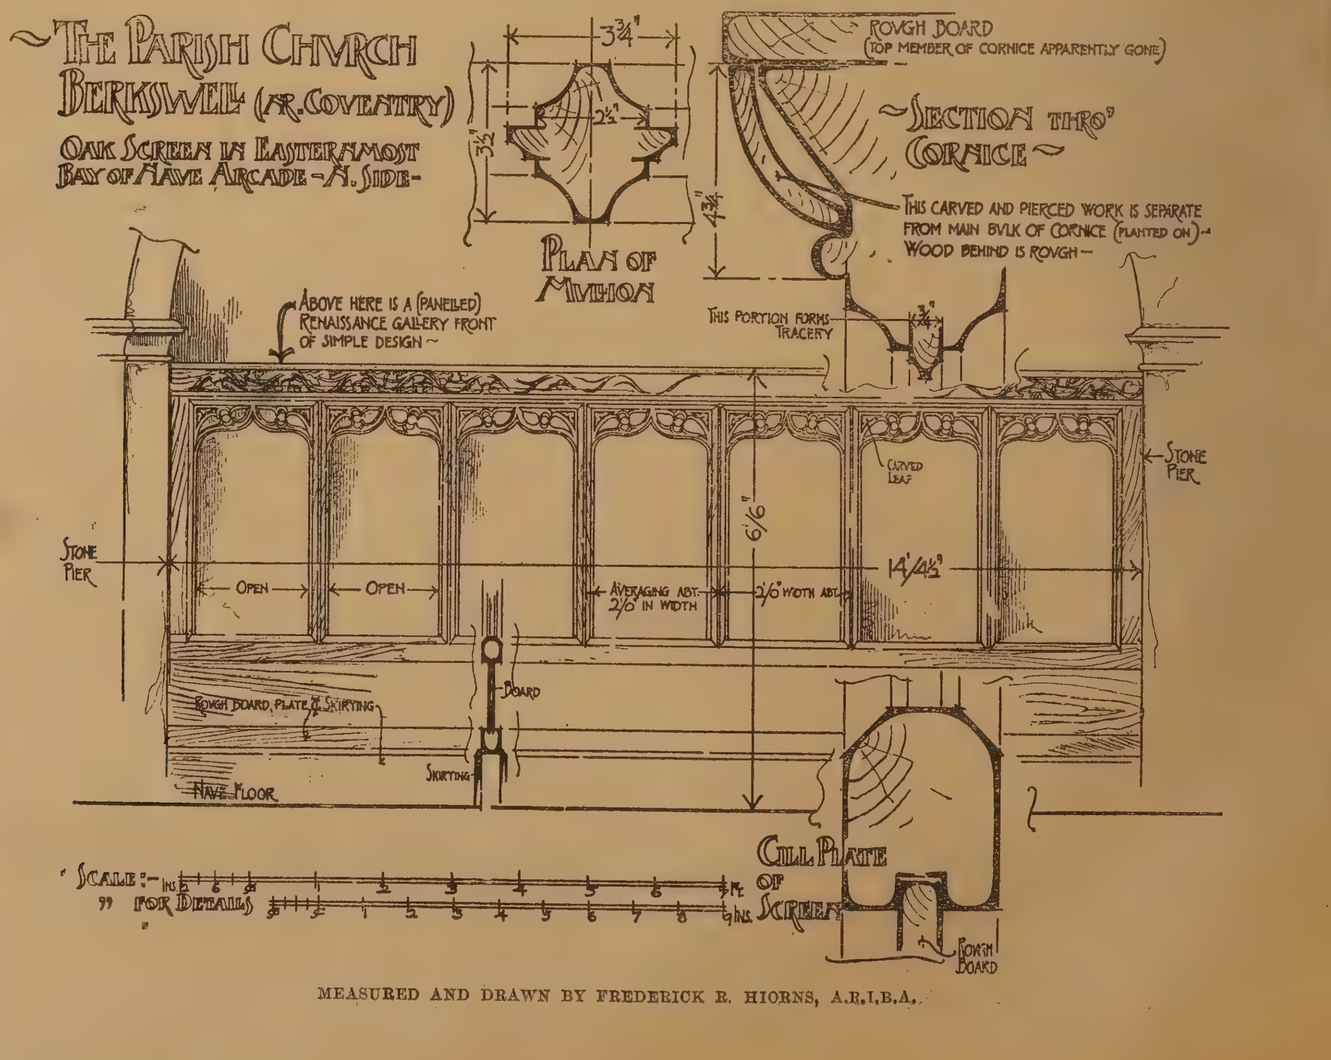
Theatre Fires. IT is so long since a fatal fire occurred in a London theatre that the general public forget this is mostly due to constant and careful supervision and more fireproof methods of construction. Occasionally, however, attention is drawn to these matters, as in the reports of the paper which Mr. Mulholland read before the Playgoers' Club on Sunday evening. Mr. Mulholland expressed approval with the requirement that a portion of the roof over the stage should be of glass, so that in case of fire it would soon give way and draw off the flames from the auditorium, illustrating his point by reference to the two fires at the Grand Theatre, Islington. When the first fire took place there was a heavy concrete roof, and the flames were forced into the auditorium; in the second fire the auditorium was practically untouched. There is more danger of the audience being stifled by smoke than actually burnt: hence the absolute retention of the outburst behind the curtain and the withdrawal there of the smoke and flames should be essential requirements.

THE ARCHITECTURE OF "ULYSSES."

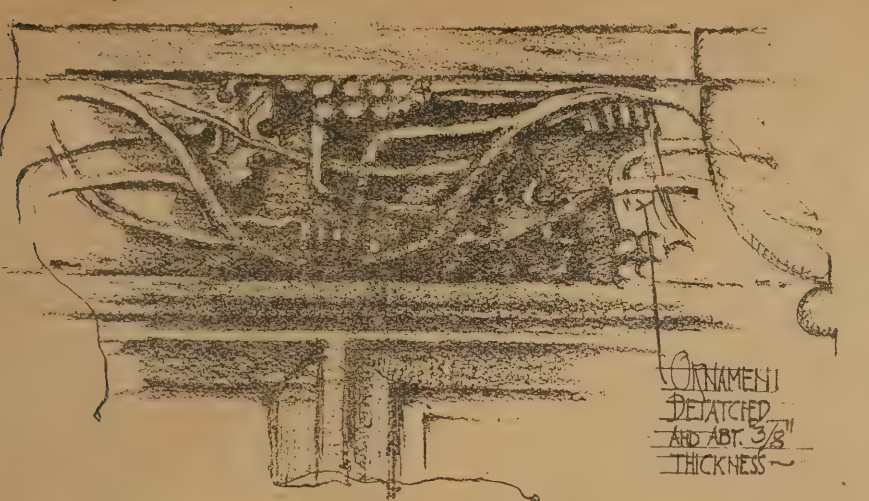
THERE is nothing more characteristic of modern plays than their great and costly settings, and in these the accurate representation of architecture is receiving increasing attention. The most notable examples of recent years have been "Julius Cæsar" and "Herod" at Her Majesty's Theatre and "Coriolanus" at the Lyceum Theatre. At no theatre are the settings so magnificent, or the multitudinous details so carefully considered as at Her Majesty's, and in the production of "Ulysses" Mr. Tree has excelled himself: the more so by reason of the great difficulties attaching to such an archaic play, requiring the widest knowledge and most thorough research in order that the scenes may be as correct as it is possible to have them. We say this because the facts about Mycenæan architecture are but incompletely revealed, though, compared with what was known before the recent wonderful excavations in Crete, they are very considerable. In presenting the architecture of this difficult period Mr. Tree has requisitioned the aid of Professor W. R. Lethaby, Mr. Sidney Colvin, M.A., and Dr. Murray of the British Museum, the two scenes representing the forecourt of Ulysses' palace on the rock-bound isle of Ithaca and the banqueting-hall in the same palace having been carried out by Mr. Harker from sketches furnished by Mr. Lethaby (who, it will be remembered, is professor of design at South Kensington). These are intended to give an idea of "that peculiar system of primitive architecture and decoration the traces of which have lately been unearthed at so many sites of legendary renown in ancient Greece. The researches of modern explorers in this field began with the work of Dr. Schliemann at Troy, Mycenæ and Tiryns. Similar explorations are being actively carried on to-day by English and other scholars, the richest results of all being those yielded by the island of Crete. The style, known generally for convenience sake as the Mycenæan, is supposed to have lasted approximately from about 1500 to 1000 B.C. It differs widely, as will be seen, from the simplicity and purity of the more familiar architectural styles of later Greece. It is far more barbaric, oriental-looking and many-coloured; all surfaces being covered with coloured patterns of a special type or friezes of animals both wild and tame; doors and columns being enriched with embossed plates of bronze, studs and bosses of glass, &c. Professor Lethaby's aim has been not to reproduce precisely any particular extant specimens of this system of decoration (which was applied in the Mycenæan age to all objects and surfaces, both great and small), but to design freely in accordance with the general spirit of the remains discovered."

In point of detail the third scene of the first Act is the more interesting of the two architectural representations. This, the forecourt of the palace, shows towards the right a wooden building about 20ft. high raised on a base of limestone and approached on one side by a few stone steps between enclosing walls. The building forms the living apartments of the women and is open at the front on the lower floor, two wooden columns being spaced between the squarely-treated "piers" at either side. Between the columns hang blue curtains having birds worked in gold upon them, while above the unbroken front of the house is decorated with panels in fresco colours. The two columns are typical Mycenæan, tapering *downwards;* they are decorated with zig-zag bands of colour, alternatively black, silver and red, while the side "piers" are striped with black, amber and white, one horizontally, the other horizontally and vertically. Mr. Evans says in his book on "Mycenæan Tree and Pillar Cult," which is really the only authority on the subject which embodies the recent discoveries made by the author and Mr. Hogarth:—The Mycenæan column in its developed architectural form essentially belongs to woodwork structure. The fundamental idea of its sanctity as a "Pillar of the House" may at times have been derived from the original sanctity of the tree trunk whence it was hewn, and a form in this way possessing religious associations may have been taken over into stonework. But there is also what seems to be conclusive evidence that among the Mycenæans pillar-supports of a very primitive form of stone construction have left their trace on the Mycenæan column in its perfected shape and explain indeed its most characteristic feature, namely, the downward tapering outline which distinguishes it alike from the columns of Egypt and the East, and from those of later Greece. In the Balearic islands examples have been found of a horizontally vaulted chamber deriving its support from a column the upper part of which consists of cross slabs gradually increasing in size so as to present the appearance of an upwardly widening pillar and capital: the object of which is to meet the inwardly inclining walls of the chamber and form a kind of Tirynthian passage all round. This is a simple explanation of the "Pillar of the House."

Some conception of this ancient cult among the Mycenæans is of great aid in studying the architecture. In these early days the pillar itself was supposed to contain the divinity, just as among other primitive races the belief existed that the rude stone monuments placed over graves were actually the dwelling-places of the ghosts of the dead. In Crete the worship of the pillar was closely connected with that of sacred trees and there is this connection between them —that the tree itself could be converted into a column or tree-pillar which still retained the sanctity of the original; and moreover was emblematical and symbolical as supporting the structure, though this was not always the case, as the columns were sometimes set outside the building and possessed rayed terminations (it is interesting in this connection to note that the two columns in front of Solomon's temple — "the Stablisher" and "in Him is Strength"—were placed there as symbols of the endurance of Jehovah, though it is doubtful whether they actually supported the roof beams of the porch). Among the features in Mycenæan art none are more noticeable than the double-headed axe and the "horns of consecration,"



MEASURED AND DRAWN BY FREDERICK R. HIORNS, A.R.I.B.A.



which, as the name implies, refer to the horns of slaughtered animals used in sacrifice, and the representation of which constantly recurs in decorative form: while as regards the double axe, it is not without interest to observe that "labrys" was the Lydian name for the Greek πέλεκυς, or double-edged axe, so that the wondrous Labyrinth of Crete was the "House of the Double Axe," or the "House of Zeus."

It should be borne in mind that the great Zeus, God of the Double Axe (the electric equivalent of which, by the way, flashes so brilliantly in the prologue of the play), was the divinity worshipped in this past age. The tomb of Zeus on Mount Dikta was shown in Crete down to at least the fourth century of our era and it was the preservation of this piece of primitive religion that gained for the Cretans the distinguishing epithet applied to them by Kallimachos and St. Paul. In Crete the pillar cult and the worship of the fig-tree were universal, the pillar, with a crude representation of a double axe cut on each of its stones, serving to impersonate the mighty Zeus. This worship had a particular influence on the architecture and we see that the pillar was looked upon as the "Pillar of the House," like the Hathoric columns of Egyptian temples or the sacred Dad or Tat pillar with its fourfold capital that was supposed to support the four quarters of the heavens.

Perhaps the most interesting part of the block of women's apartments shown in the play is the roof. This is composed of three rows of round timbers laid at right angles to one another, so that the middle row shows only its ends at the front, which give the effect of a very crudely-moulded cornice: an exact representation of which is seen in the famous tympanum relief of the Lions' Gate at Mycenæ, where between the sacred animals is set a typical Mycenæan column supporting a fragment of the roof beams.

The roof timbers project about 3ft. at each side and are supported by struts which stand out from the front of the building at an angle of about 45 degs.: but as to what is their exact construction one cannot say, though it appears that they are tenoned in position. Above the roof a low dome pierced with holes excites the curiosity (it apparently serves as an outlet for the smoke from the fire within the room), while above it is a square tower wherein men may keep watch over the approach to the palace. To the right of this block is a covered way smothered with creepers and fruit vines, through the wall of which access is obtainable to the orchard and the town beyond. This lean-to, for it is nothing more, has a most curious ridge decoration which recalls the "guttæ" of the later Greek period, when, however, they were placed at the *edge* of the roof. The posts supporting the roof are painted with alternate black and white bands which might appear to be an adapted form of the "horns of consecration," but are more probably a decorative treatment of the mortice and tenon joint, like that in the fresco discovered at Knossos.

To the left of the women's quarters runs a low battlemented wall of ashlar masonry, having a kind of platform for the archers behind it decorated with a band of what might be called a prototype of the egg and dart ornament: beyond are the hills of Ithaca. Within the space thus enclosed is a courtyard and on the left side one sees the corner of a pedimented wooden building having the characteristic tapering pillar, with surface decorations in gilt, silver and colours.

The other architectural scene in the play is that of the banqueting-hall inside Ulysses' palace: and of this so much need not be said, for there are many similar features which have already been described. The apartment is oblong and at each side of the centre is a decorated column having a roughly floriated capital, Egyptian in feeling, while the roof is hung with decorated cloth having a black and white pattern, with strips of green and yellow extending from pillar to pillar and thence to the sides of the room. In the fragments of fresco discovered at Knossos a black and white checker pattern is seen which is doubtless taken from stonework construction and probably copied from Egypt, though the builders of the Palace were quite capable of producing stucco imitation of masonry: and it is just possible that ceilings may have been plastered and decorated somewhat similarly.

Around the top of the walls in the banqueting-hall is a deep frieze decorated with Mycenæan scrolls in red, with green diamonds between them, while the remainder of the wall-surface consists of a great fresco painting having a blue ground whereon brown lions leap, shot through with great arrows, other arrows, and birds, also being included in the decoration: altogether a very bold and effective scheme. To the left of the banqueting-hall a few steps lead down from Penelope's private apartments; on the opposite side is a door covered with bright metal; and at the back is the main entrance to the hall surmounted by a great representation of the sacred tree with a smaller tree on either side below its branches.

These then are the two scenes. They are both striking in conception and barbarously grand in effect, and not the least interesting features in them are the numerous details which were afterwards to be developed and perfected by the later generations of Greeks.

The Nottingham Architectural Society held its annual dinner last week. Mr. A. Marshall (president) was in the chair, and Mr. A. W. Brewill (vice-president) in the vice-chair.

The Oak Screen in Berkswell Church, near Coventry, shown in the accompanying illustrations by Mr. Frederick R. Hiorns, A.R.I.B.A., is one of several in the nave arcading of this interesting old church, some particulars of which were given on p. 295 of our issue for December 11th last.

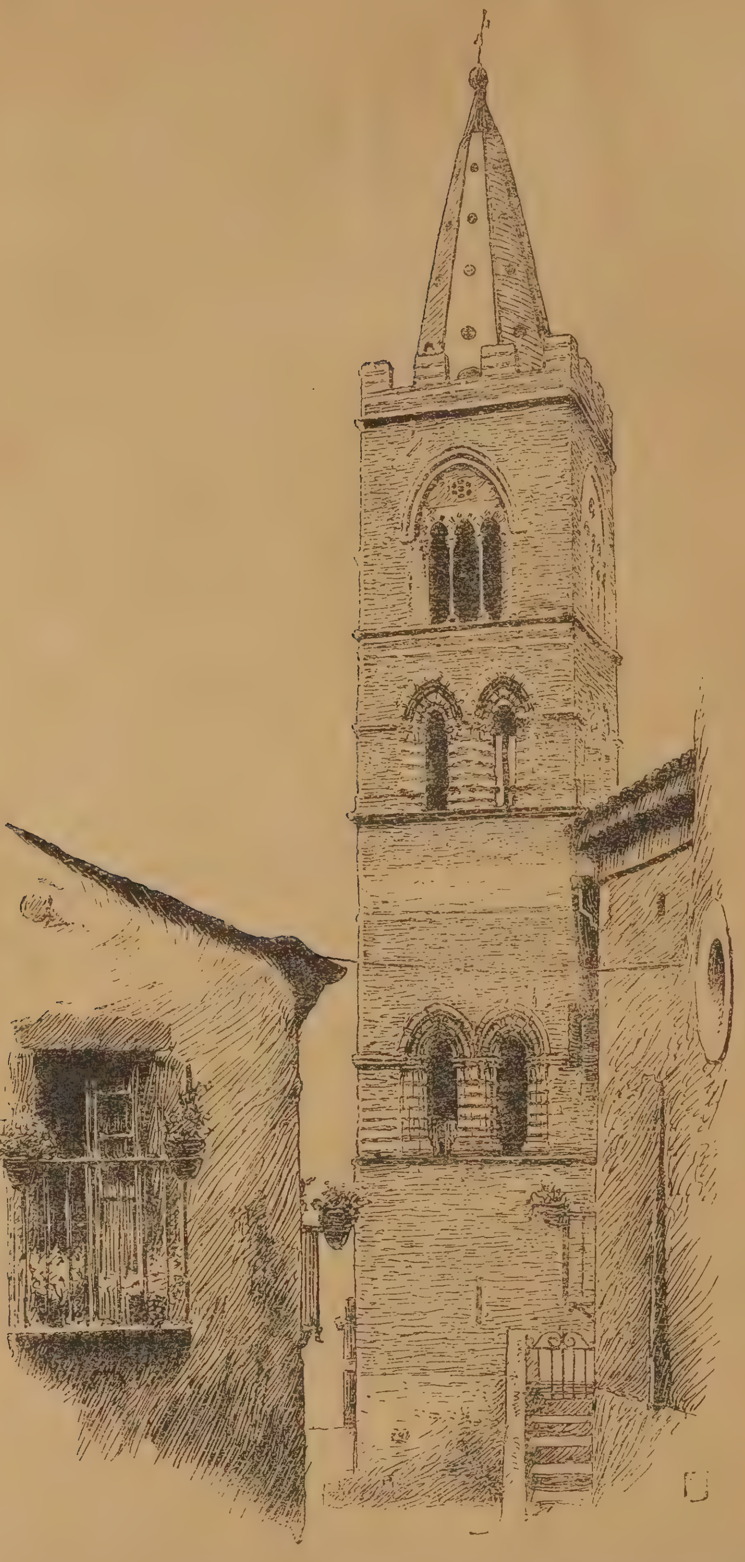
SICILY AND ITS ARCHITECTURAL MONUMENTS.—III.

By F. HAMILTON JACKSON, R.B.A.

(*Continued from p.* 411, *No.* 364.)

THERE is, however, another and perhaps more interesting route to Catania than that described in the last article, namely, by the Circum Etnea line, which starts from Riposto near the station on the main line and returning northwards to Piedimonte passes round the mountain on the landward side, affording most picturesque views from its slopes over the plains and towards the mountain chains of the interior, and passing many places of considerable interest both from the historical and artistic side. The line runs at first up the valley of the Minissale along the slopes of Etna, and looking across to the lesser hills which divide it from that of the Alcàntara. Before reaching Linguaglossa the remains of the eruption of 1566 are traversed, now cultivated for the most part. Here the land is covered with vineyards, while a little further the best hazelnuts in Sicily are grown. On the other side of the valley highly-placed towns look picturesque on their lofty sites, almost like towns from the backgrounds of mediæval pictures. Near Mojo station the lava descended in 1879 almost as far as the Alcàntara, which runs along the valley below, and the people of Mojo, which lies on the other side of the river, became alarmed and brought out an image of St. Anthony, their patron saint, in procession to stop it. This lava is not yet disintegrated at all, and presents a very ugly appearance, something like the slag of a smelting furnace on a large scale, the only thing growing on it being a giant spurge. Near Mojo is an interesting little Byzantine church of the seventh or eighth century. Square in plan, with a flat cupola roof and a small apse on each of three sides, the entrance is on the fourth. This is said to be the only Byzantine church in Sicily, above ground, anterior to the Saracen invasion, and curiously enough the peasants' name for it is "La Moschea."

Randazzo lies at the top of the valley of the Alcàntara, and though it contains but 8,500 inhabitants is a place of some importance. It was founded by a Lombard colony and was surnamed Etnea by the Emperor Frederick the Second as being the nearest town to the crater of the volcano. The manners of the people are rough and the town still preserves a severe and warlike appearance worthy of its mediæval origin. The Aragonese kings often spent the summer here, thinking the air healthy. Perhaps the severe appearance of the town is partly owing to the use of lava for building relieved by plaster and whitewash in the less constructional parts, a mode which chastens the exuberance of the later Renaissance with advantage, but does not so well set off the earlier Gothic building. The choir of the church of S. Maria dates from the thirteenth century, and the side walls from the fourteenth. It towers up from the street like a fortress with a machicolated cornice. The ornament is based on Byzantine data roughly cut and with the addition of details which are Norman (the billet moulding and other details) and Renaissance (vases bearing flowers and arabesques on pilasters). The campanile is a curious modern concoction of the confectionery order put up in 1873, when the church was restored. The name of Petrus Tignosus appears in an inscription as the first architect. The interior has an arcade of great lava columns with roughly-cut caps of early fourteenth-century type, the walls are whitewashed and the roof covered with particularly abominable frescoes, which, like the pictures above the side altars which vie with them, are the production of local talent and date from the seventeenth century, when the interior was recast. The large church of St. Martin at the other end of the town is of the fourteenth century. It has a fine tower of lava with courses of white stone here and there and the walls finish with an interesting corbel table bearing some resemblance to the machicolations of S. Maria. Opposite is the old Ducal Palace, now a prison, still bearing the spikes on which the heads of criminals were exposed. Many of the houses appear to be mediæval, quite small places with pointed



CAMPANILE OF S. MARTINO, RANDAZZO. DRAWN BY F. HAMILTON JACKSON, R.B.A.

windows on the first floor and a row of quatrefoils below them, as well as the larger houses of more wealthy citizens, and there are also a good many palaces of considerable importance and of different dates. In the main street are several very picturesque seventeenth-century shops consisting of a full-centred moulded arch, sometimes with carved keystone or caryatid brackets, beneath which are counters on each side of the entrance, sometimes supported by consoles of robust outline and always projecting well beyond the wall face with a boldly-moulded edge of two or three members. There is also some good ironwork in the shape of fanlights of late date. The church of S. Nicolò stands in a little piazza to the side of the main street approached by a passage across which a thirteenth-century house was once thrown. The arches which supported walls and floor still remain and a portion of the front wall, pierced by a graceful two-light window with twisted shaft. The church contains some sculpture ascribed to the Gagini, almost the only Sicilian sculptors known to fame; a family which came from the north of Italy and after three generations returned to its birthplace. The tradition of Florentine design is visible in their work and occasionally the execution of it, but very occasionally. The dome of S. Nicolò was in fragments on the floor and extensive works of reparation were in progress. The façade is an example of what has been said about the chastening influence of the use of lava in building upon the licence of curve used by the later Renaissance architects.

From the railway the retrospect of Randazzo is charming, and an artist might do worse than stay in the town for some time, though the hotel is rather primitive and it would be best to make a bargain about prices before commencing a lengthened stay, since the argument was used to us that the small number of visitors made it necessary to charge those who *do* come highly! The line still ascends until Brontè is reached, passing Maletto on the way, a small town with an old castle, below which lies the suppressed Benedictine monastery of Maniacum, founded in 1174 by Margaret, mother of William II. Maniace, the town near, where the steward of Viscount Bridport lives, takes its name from the Greek general Maniaces, who also built or recast the castle of Syracuse. Here in 1040 he defeated a large army of Saracens, aided by Harold Hardradr and his Norwegians and a contingent of Normans. Brontè is said by some to be a very ancient town, while others state that it has been built since the time of Charles V. The line circles round it on a higher level, almost as if on the upper seats of an amphitheatre, over the lava of 1651, which descended close to Brontè. Its name is said to come from one of the Cyclops of Vulcan's forge, and to Englishmen it is interesting as being the place which gave the title of Duke of Brontè to Nelson. This is a good point of departure for lofty Troina, 1,000ft. higher than Castro Giovanni and the loftiest of the larger towns of Sicily, where Count Roger and his young wife Judith were besieged by Greeks and Saracens in the bitter winter weather when they had but one cloak between them. The views are now over the beautiful valley of the Simethus and many lava flows are crossed before arriving at Adernò, the most important sub-Etnean town after Catania and Aci Reale. Here the famous temple of Adrano stood, guarded by more than 1,000 dogs. The city was founded by Dionysius of Syracuse, and it flourished under the Saracens. Roger fortified it, erecting a castle of which one tower is thought to remain, though recent discoveries have made this doubtful. Here his niece Adalisa took the veil in the convent of Santa Lucia, which he founded in 1157. It is said that until the eighteenth century the women of the people used to dress in the Greek fashion with a long white chlamys, and the nobles used the costume of Spanish gentlemen of the sixteenth and seventeenth centuries. Truly a picturesque people amid picturesque surroundings in those days! Below in the valley are the remains of a Roman aqueduct. The line now descends rapidly to Bianca villa, which is inhabited by the descendants of Greeks, Albanians and Epirots who took refuge here from the Turks in the fifteenth century. Paternò, seven miles further on, is a town said to have been founded by the great Count, who built the castle and gave it as a dowry to his daughter Flandrina when she married Henry the Lombard. Antique sarcophagi and sepulchres discovered here prove it to be older, and it seems probable that it is on the site of the Siculan city of Hybla Minor, since two arches of an ancient bridge are still standing and the road from Catania to Centuripæ passed by Hybla. Motta S. Anastasia has an ancient Saracen castle something like La Cuba at Palermo, restored by the Normans, and from hence to Catania is but a short distance.

Catania, which after Palermo is the most populous city in the island, is the seat of a bishop, of a court of appeal, and of a university, which was founded in 1444 by Alphonso of Castile. Being a prosperous town and having suffered, as it has, from earthquakes and eruptions, there are very few antiquities of interest left, but among the few are two or three which make it worth while to stay there for a short time, and the history of the place demands a few words. The cathedral is dedicated to St. Agatha, who was martyred in 93 A.D. under Diocletian as some say, or as others assert under Decius in 252 A.D. The veil with which she is said to have covered her breasts is now considered the most powerful talisman of the city against the flowing lava. Her chapel is to the right of the altar and contains her shrine and the half-length statue of her, bearing the crown given by Richard Cœur de Lion. These are most elaborate and beautiful examples of the goldsmith's art of the fourteenth century and were made by Giovanni di Bartolo of Siena. The shrine is surrounded by niches filled with statuettes and is also decorated with jewels and enamel. The apses of the cathedral are decorated externally with a pointed arcade without mouldings; they and part of the eastern transept are the only parts of the original cathedral founded by King Roger in 1091 still existing unaltered. The six granite columns in the present façade came from the Greek theatre, from which King Roger seems to have obtained most of his building materials. The fountain of the elephant in front of the cathedral consists of a figure of an elephant in lava, of extremely ancient date, bearing on its back an Egyptian obelisk of granite which was found on the site of the circus, surmounted by an iron cross, crown and lilies, on a base of marble with figures of the rivers Simethus and Amenanus. The doorway of the church of Santo Carcere, a fine Greco-Norman piece of work, was taken from the cathedral, to which it belonged, after the earthquake of 1169. It is said that St. Agatha was martyred here, and they show her cell and the print of her foot on a piece of lava. The only other mediæval monument is the Castel Ursino, built by Frederick II., at both sides of which the lava flowed in the eruption of 1669. It is square with round towers at each angle and one extra flanking the entrance, covered with a sort of bombproof roof from which a little dome rises. The whole building is now plastered and no details show.

The Greco-Roman theatre from which Roger took the materials for his cathedral is within the precincts of houses built upon portions of its walls. The seats, of which only twenty-six rows remain, are hewn out of tufa and covered with limestone slabs, and have still a few pieces of the marble which overlay those *in situ*. Part of it is underground, and the stage, which probably exists under other houses, has not yet been excavated. Of the amphitheatre still fewer remains exist, a few arches in the Via Archibusieri, which is perhaps scarcely to be wondered at, since as early as 498 A.D. a decree was issued by Theodoric allowing the citizens to use it as a quarry wherewith to repair the walls and other buildings damaged by earthquake and the barbarians. Its length was 138yds., the breadth 116yds. Near to it are a few remains of the Greek aqueduct, which once brought water from below Licodia, seventeen miles away.

The modern town has broad streets as well as squalor and dirt, and the florid belfries in the baroque churches which frequently rise at the end of a street contrast strikingly with the straight lines of the street fronts. The Via Stesicoro Etnea, the longest and most important, starts from the Piazza del Duomo and passes several piazzas which contain the University and Municipio and the Prefecture, leading to the Villa Bellini, the show-garden of Catania. Two other places must be mentioned, the Roman bath which lies under the Carmelite church "All' Indirizzo," and is almost complete, and the suppressed Benedictine monastery of S. Nicolà with two large courts, now used for barracks and for scholastic purposes. The immense unfinished façade of the church, which possesses an organ which is one of the finest in Europe, looks upon a dreary and squalid piazza.

The plain of Catania was the spot in which the first cities of the Sicanians were built, and here the first historical ideas of Sicily commence with Xutho, son of Æolus, king of the Ephestads or Æolids, called by the Sicanians with his brothers to govern them. This was sometime before the Greek epoch began with the Trojan war.

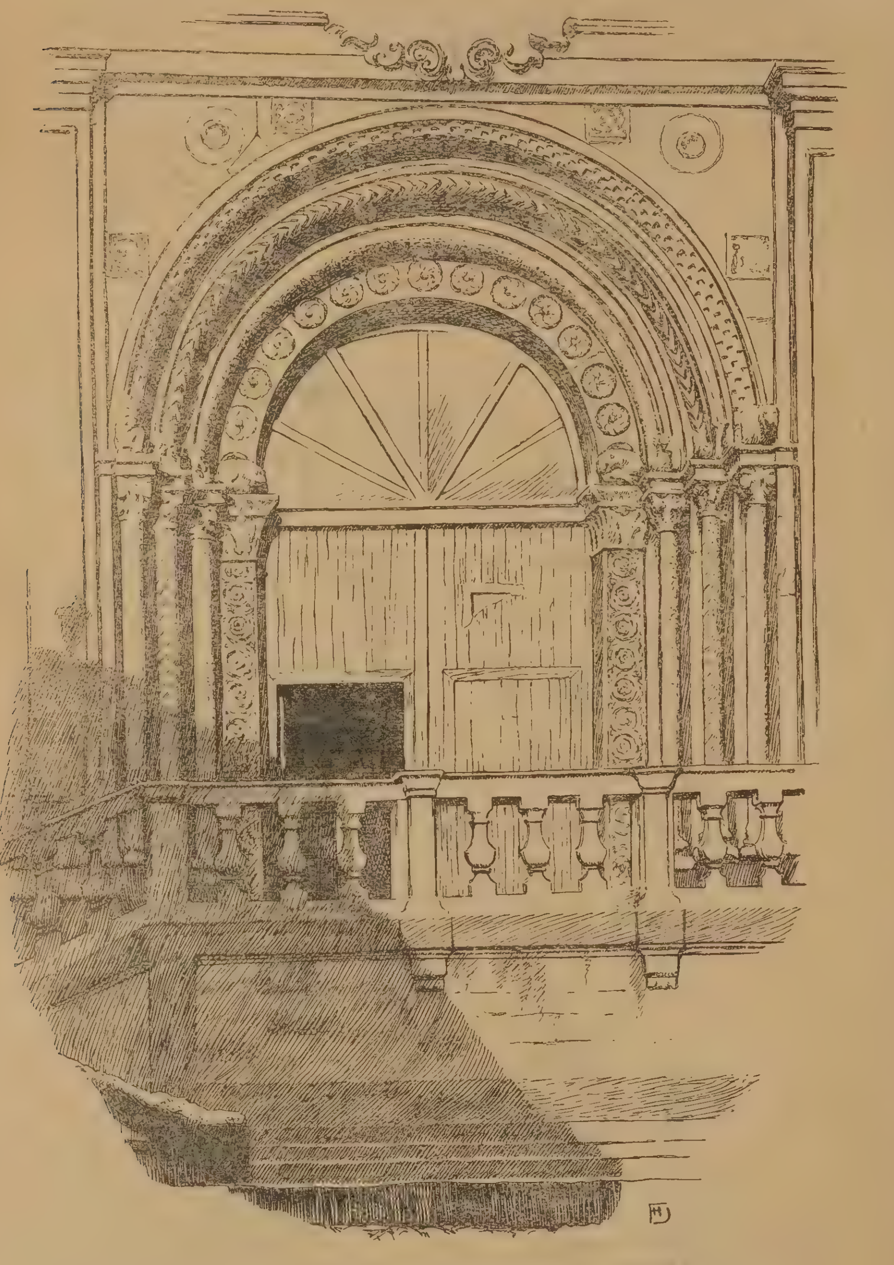
Catania was the centre of Sicanian culture, and here was the great temple of Ceres, as celebrated as the Ceres of Enna. The festivals of the Catanian Ceres, called Ambarvalia, preceded if they did not surpass in fame the Eleusinian mysteries. The sixth century B.C. was for Catania a century of splendour and liberty in which it rivalled Syracuse and Agrigentum. It was enriched with temples, it had a hippodrome for Olympic games, celebrated the most solemn Bacchic feasts in all Sicily, had a Naumachia for naval shows and a theatre for comedy and tragedy, an Odeum for music, a Basilica, public granaries, a mint and an armoury. The gymnasium and academy were then the most celebrated in Sicily. Here Stesichorus lived, the great poet who invented the strophe, antsitrophe and epode of the theatrical chorus, and the forms of epithalamium, elegy and hymn to celebrate the glory of heroes, of poets and of his country. Here too lived Charondas the legist whose laws for Catania were adopted by many of the cities of Sicily and Magna Græcia, and to whom the glory of establishing free education is due, whose respect for law was so great that having unwittingly

PASSAGE LEADING TO S. NICOLO, RANDAZZO. DRAWN BY F. HAMILTON JACKSON, R.B.A.

transgressed one of his own laws by entering the Forum armed while the Senate was deliberating, the penalty for doing which was death, he turned his own arms against himself and fell dead. In 474 B.C. Hiero I. took the town, removed the citizens to Leontinoi, colonized it with 10,000 Syracusans and Peloponnesians, changed its name to Ætna and died in it. So wholesale were the methods of conquest in those days! This was the first of several conquests of Catania by the Syracusans, and the city also suffered much at the hands of the Romans during the civil wars, although at first it prospered under their sway and became one of the most populous towns of the island. Reduced to insignificance during the early middle ages, and destroyed by the troops of Henry VI., the Suabian, it was restored and fortified by his son Frederick II., and under the Aragonese sovereigns of the fourteenth century was the usual residence of the Court. Since that time, except for the revolutionary disturbances of 1848 and 1860, it has had more to suffer from earthquakes and eruptions than from the fury of man.

(*To be continued.*)

The Queen Victoria Memorial Fund now amounts to about £189,000.



DOORWAY, OF SANTO CALCERE, CATANIA. DRAWN BY F. HAMILTON JACKSON, R.B.A.

Law Cases.

A Case affecting Verandas.—At the Blackpool Police Court recently Messrs. Robert, William and Thomas Field, builders, were summoned by the Corporation for an alleged breach of the bye-laws. They are the owners of 28, Dickson Road, part of which was a lock-up shop. In May last year a plan of a veranda was submitted to the Corporation. The plan was disapproved but the veranda was built. It was 8ft. above the street and 15ft. long. Richard Bamber, building inspector, held that a veranda was a building. Defendant's counsel contended that if this were so, then there were other verandas which projected as far as the one in question. He asked how it could be urged that they had extended a building beyond the front when the same was a veranda. The Bench found that though the veranda was a building, the written permission of the Corporation was not necessary for construction. They therefore dismissed the case.

The Tapestry Case.—The appeal case of *Leigh and Others* v. *St. John Stewardson and Others* came before the House of Lords on Thursday last. This was an appeal relating to seven tapestries in the drawing-room of the mansion-house at Luton Hoo, Bedfordshire. Mr. Justice Byrne held that they were fixtures, but his decision was reversed by the Court of Appeal (as reported in our issue for February 13th, 1901). John Gerard Leigh, of Luton Hoo Park, who died in 1875, bequeathed to his wife Madame de Falbe all his furniture, &c., and personal estate excepting leaseholds for her absolute use and benefit, and bequeathed to her all his freehold, copyhold and leasehold estates for her life, and after her death to his heir-at-law. Before 1886 Madame de Falbe affixed the tapestries, the subject of the appeal, to the walls of the drawing-room. Mr. Justice Byrne held that they were fixtures and formed part of the mansion, and could not be removed by Madame de Falbe's executors. The Court of Appeal, however, held that they were chattels belonging to the estate of Madame de Falbe, and reversed the learned judge's decision; and this view of the case was upheld by the House of Lords last week in dismissing the appeal. The Lord Chancellor said the tapestries were placed over stretched canvas affixed to the wall by wooden battens. He did not know of any other mode by which they could—one was 14ft. long—be placed on the wall. They could easily be removed; in fact they had been removed without any disturbance to the wall. These tapestries were pictures in another form, and it would be extraordinary if they were intended to be dedicated to the house. He was of opinion that they did not pass with the house for the benefit of the inheritance.

An Ancient Lights Case.—The case of *Parker* v. *W. F. Stanley & Co., Ltd.*, came before the Chancery Division of the High Court of Justice last Saturday. The plaintiffs in this action carry on business as photographers at 288, High Holborn. When they first entered into possession, in 1890, the studio and gallery, a one-storey building at the rear of the premises, was lighted by a number of skylights which were ancient lights. The plaintiffs subsequently slightly altered the pitch of the roof of the building and enlarged the skylights over the studio, but they darkened or obscured the skylight over the portion of the building used as a dark-room. To the west of the plaintiffs' premises is a long strip of land about 15ft. wide, which was formerly partly bounded on the western side by an old building about 33ft. high, pulled down in 1885. In February, 1901, the defendants commenced building operations on the site of the old building demolished in 1885, and since the issue of the writ in this action have raised their building to a considerable height above the line of this old building, whereby the plaintiffs complained that the access of light to their premises was seriously diminished. Mr. Justice Farwell in delivering judgment said that there could be no doubt that when the plaintiffs took the premises in 1890 the skylights were ancient lights. As regards the dark-room, abandonment had been pleaded, but he could find no evidence to support the plea. The fact that the plaintiffs had darkened or obscured the skylight was not sufficient; the room might be required at any time for other purposes. Then, with regard to the studio, the old skylight had been replaced by what was practically a glass roof. But that new glass roof covered the place occupied by the old window, and their right of ancient lights had thus been preserved, although, of course, it only applied to that portion of the glass roof formerly occupied by the old window or skylight. The defendants had raised their building several feet above the line of the old building which formerly stood on the site, and after hearing the evidence his Lordship was clearly of the opinion that the access of light to the plaintiffs' premises was thereby materially diminished. Photographers required, and reasonably required, special light, and since the judgment in *Warren* v. *Brown* (1902, 1 K.B., 15) the plaintiffs were entitled to complain that they were injured by the defendants' buildings in the conduct of their photographic business, even if that business had not been carried on in the premises for twenty years. The parties had not been able to come to any terms, and consequently he was constrained to grant a mandatory injunction, but it would apply only to the additional obstruction caused by the defendants' new buildings as compared with the old buildings that formerly stood on the site. He thought the parties ought to be able to arrange between themselves what form the necessary alterations should take.

HORISM FOR THE WEEK.

ilt by that only law, that use be the suggester
of beauty,
thing concealed that is done, but all things
done to adornment.—CLOUGH.

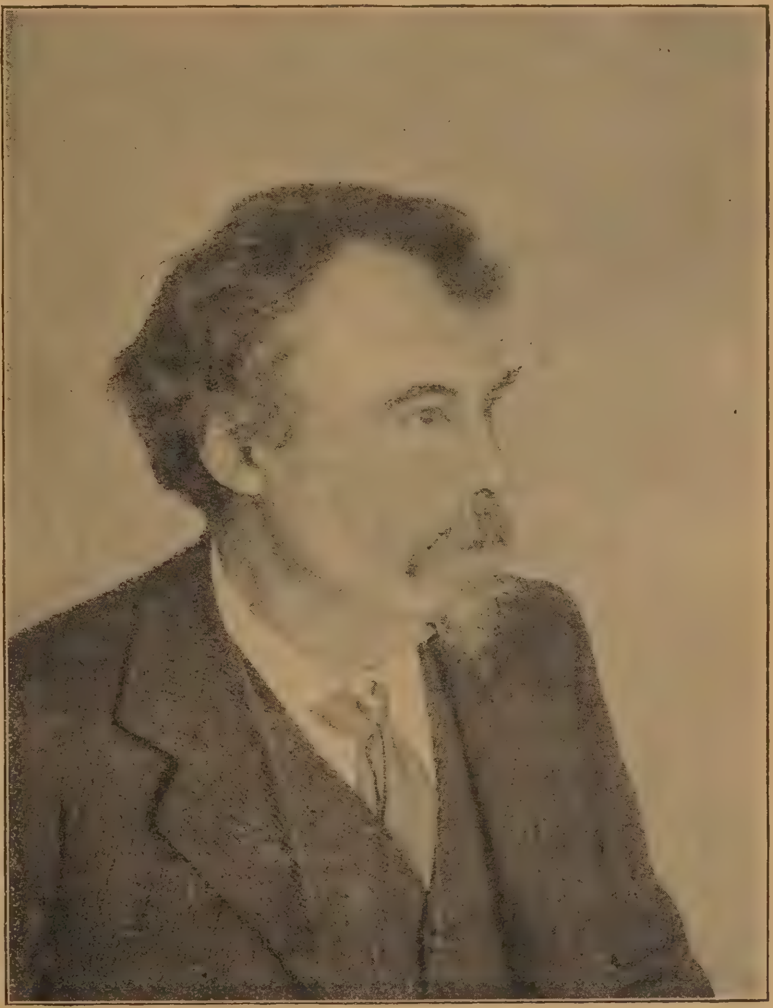
Our Plates. FROMOND'S CHANTRY, Winchester College, was erected thin the cloisters as a chantry for the ad, and founded by John Fromond in the teenth century. The ground floor measures ernally 36ft. by 18ft. by 27ft. 2in. to the lge of the vaulting, the ceiling being divided to two equal bays of Lierne vaulting. There is solid stone altar at the east end. The first or measures 36ft. 11in. by 18ft. 11in. by ft. 6in. high and is covered with a plaster iling. This floor, compared with that under- ath, is very plain, with the exception of the o end windows. There is a circular staircase in urret at the south-west corner, a gable at each d and an embattled parapet both sides. The apel was converted into a library during the formation, but has since reverted to its former e, and is now used as an "overflow" chapel r the college, the first floor being still occupied a library. The drawings are by Arthur H. hnson, of Winchester.

The Liverpool athedral Com- ttee's Pamphlet. MR. T. MYDDLETON SHALLCROSS, hon. secretary (pro tem.) of the Liverpool Cathedral Petition Committee, says of c pamphlet in question that it "chiefly consists a mere reprint of the misleading statements ich have appeared in the press from time to ne, and which have then been shown to be correct and not at the time further contested. e value of the St. James's Mount site is stated be only 'a little over £10,000' (*i.e.*, the cost of ising the mound and laying it out many years o, and not its present market value), whereas eir own diocesan surveyor, Mr. Bradbury, has lued it at £20,000, and the Corporation surveyor, r. Shelmerdine, at £35,000, and both of these luations are probably less by some £60,000 to 70,000 than the actual market value of the site d houses. On the other hand, however, onument Place site is stated to be worth over 200,000, without trade compensations, although r. Bradbury and Mr. Shelmerdine have each lued it at £130,000, with £50,000 for trade mpensations. Again, it is stated that there a railway tunnel underneath the corner of onument Place site 'which might prove a urce of very great inconvenience'; but no ference is made to the fact that another ailway tunnel' is close to the St. James's ount site, which, were there any real objection either case, might prove an equal source of convenience. . . . The pamphlet suggests that e St. James's Mount site has been selected cause it is the best and not because it is cheap. et Lord Derby stated at the Town Hall meet- g in June last that its selection was due to otives of economy; and it is a fact that the athedral Sites Committee reported that Monu- ent Place site was the best, and recommended s adoption."

Indian Victoria Memorial. LORD CURZON, the Viceroy, has issued a long note with reference to the Victoria emorial Hall. His Excellency says that irty lakhs of rupees have been promised and at more are expected. A Building Committee needed. During the past year attention has en given to the questions of style, site and aterial. It would be useless to attempt to ect a modern Taj in the Classical style. The st material would be white marble, as far as ossible Indian. With regard to the site the lternative suggestions have been found unsuitble, and the original selection will be adhered , the main front of the building being to the est. With reference to designs, the note ontinues, the Viceroy has conferred with Mr. merson, the President of the Royal Institute f British Architects. It is essential that the uilding should be several feet above the round in order to secure a foundation for the roposed terrace, 400ft. long, which is to run long the front of the building. The building tself will occupy a parallelogram. The Queen's Hall in the centre will contain a statue of the Queen only. Mr. Frampton's statue will be at the entrance. On the left hand there will be a sculpture gallery, and on the right a picture gallery. Room will also be provided for various other collections The grounds will be thirty acres in extent, and will be fenced. Additional funds are needed for the building and for its upkeep and endowment, and for the purchase of the contents.

The Archers' Hall, Edinburgh. THE old building which for long has in a way been a conspicuous figure standing back from the thoroughfare in Buccleuch Street, Edinburgh, has been reconstructed from plans prepared by Dr. R. Rowand Anderson. The original structure formed a square of about 40ft. All that remains of it now are the outer walls. An addition has been made at the south end, and the piece of ground which stood open in front has been enclosed with ornamental wrought-iron railings and gates. As reconstructed the hall of the Royal Company of Archers consists of three floors. The basement is given up to kitchen, and scullery, housekeeper's rooms, &c. The first flat includes a large entrance hall with cloak-room and lavatory accommodation running off it. Occupying the entire length of the old building on the west side is the reception-room. The dining-hall is on the upper floor and fills the whole area of the old building.

Structural Ironwork. AT the monthly meeting of the Leeds Association of Engineers, Mr. Alfred Towler in the chair, Prof. John Goodman read a paper on "Structural Ironwork." The value of building sites in big cities, he said, had risen to such an extent that a structure could now only be made to yield a reasonable return on the outlay by making the best possible use of space. For ome buildings stone, brick, &c., answered admirably, but in their use for very high buildings serious difficulties arose. Mild steel was, roughly, seventy times as strong as stone in tension, seven times in compression, and ten times as rigid, whilst lending itself readily to structural purposes. Some years ago there was a prejudice against the use of steel made by the Basic-Bessemer process, but now structural steel was turned out by this process practically equal in every respect to that made by the acid-open-hearth process. For filling in, materials were required that would resist the weather, and thus by using those best suited to the purpose the highest art was arrived at. Professor Goodman gave examples of steel skeleton buildings. Columns, he said, should approximate as nearly as practicable to the hollow circular section. This was illustrated by diagrams of curves showing the relative strength of various sections according to Rankine's modification of Gordon's formula. Other curves showed their relative cost. A column should be centrally loaded, a fact which was often depreciated by architects. For a hollow circular column 30ft. long, 12in. in external diameter, and 1in. thick, the safe load applied at the axis was 116 tons, but 1in. from the axis only 31 tons. Though the action of fire on steel was too big a subject to be dealt with, experience had shown that a properly constructed steel frame would withstand fire better than brickwork or masonry, because distortion through expansion was of little consequence.



J. F. BENTLEY, ROYAL GOLD MEDALLIST, 1902.

The Royal Gold Medallist, 1902. MR. J. F. BENTLEY has been named as the fitting recipient for the Royal Gold Medal this year—"for his work as an architect"; and no better choice could have been made. His greatest work is his last—Westminster Cathedral, one of the most original buildings in recent times. A "Men who Build" article dealing with Mr. Bentley appeared in the BUILDERS' JOURNAL for July 9th, 1895.

ANCIENT VERSUS MODERN BUILDING.*

I AM glad to have an opportunity of addressing an important assembly like this, recognising as I do that your Association is formed to meet the needs of the present day in a practical way and to make an effort to devote your leisure hours to the pursuit of that which will enable you to become more proficient in your craft and carry out your work in the best possible way.

To stand before a grand old building which has stood the test of time, to think of those who wrought in it and whose work remains a monument of their care and labour—this is an inspiration. We shall notice in such a building how very carefully the so-called minor details—the beds and joints of the stonework (even of parts out of sight), the framing and jointing of the timbers—have been carried out. And let the question be put: "Is modern building work equal to this ancient work?" In this particular I am not now speaking of design—that is a matter with which, from our position as craftsmen in modern times, we have very little to do. I refer more particularly to the work or the matters which come under the control of the builder and his men. There are several considerations which enter into the case. We must first remember that only the *best* of the ancient buildings remain. There is, for instance, the Colosseum at Rome, but we do not see the square miles of buildings which once formed the houses of the Romans; and although in such remains as those at Pompeii there is plenty of evidence that there was very much good work done in the building of houses, yet there is no real reason to believe that the smaller ones were any better built than those of to-day. In former times every workman was proud of his craft, every good workman prided himself in his dexterity in it, and work seemed more human when men were allowed a large amount of freedom in executing it. The man was not merely one of 500 "hands" in a shop or a factory, but he was the carpenter or the mason or the smith who, within certain limits at least, could deal with his timber or his stone or his iron exactly as he thought best; he could put his own fancies into it, and, above all, get credit for them when he had done so.

Work done under these conditions must have been much more inspiring than that which is done according to the mechanical methods of to-day. It was possible then for a man to rejoice in his labour, but in the modern building you look in vain for the corresponding sign of free and lavish craftsmanship. Yet, though we do our work under new conditions, we need not envy the past nor entirely despair of the future, for the good qualities that animated the old work are not all dead.

Some attempt has been made in recent years to remedy the system which separates the designer from the craftsman, and we have the various guilds of arts and crafts, who no doubt are doing a very useful work in training workers both to work skilfully with their hands and at the same time exercise their own ingenuity and give expression to their individual ideas; and there is a marked difference between work so produced and the smooth mechanical product of modern machinery. Let me say here that the influence of good or bad work upon the character of the worker himself is great. A mason who is accustomed to make bad and careless joints, a joiner who habitually frames his work together faultily, will have his own moral ideas and sensibilities dwarfed and his sense of justice blunted. Life was meant to be worth the living; and work was meant to be worth the doing.

What then is the difference between the old buildings and the new?—for it is patent to everyone that modern building *is* quite different in spirit and character to the old. In the old there is exhibited a carefulness in the selection of materials and an intelligence in the working of them which I think is greatly if not wholly lacking in modern work, and not only so, but the materials themselves which are now used are much more largely of the manufactured class, bearing the mark of the machine and, as a consequence, suffering from dulness and flatness

It is said that Nature abhors a straight line; at any rate it is very difficult to find one, in flower or leaf, in tree-trunk or branches, in the face of the earth itself or the living creatures on it.

The stone in the old buildings was rough and showed the marks of the hammer that dressed it: in the new buildings we see carefully combed Bath stone. The old bricks were hand-made, uneven in shape and often of many tints, built with a certain sweetness of freedom and a disregard for a perfectly level or straight mortar joint, whereas nowadays we mostly use bricks of a monotonous colour, pressed perfectly square by the most modern machinery, and, as the specification provides, with "neatly cut and struck joints."

We have many beautiful examples of the old work throughout the country, and one very close to our own doors—at Aston Hall. This building was built by Sir Thomas Holt in the reign of James the First, in the early part of the sixteenth century. The bricks used in its construction are about 11in. long and 2½in. thick with a mortar joint ½in. thick, and although four centuries have passed since its erection and the mortar joint is a wide one according to our present-day ideas, yet it has well withstood the ravages of time and weather and only the outer surface has peeled off. On a close examination it will be found that the mortar was made with a very gritty sand, which adds to its appearance.

The timber in Aston Hall is nearly all of English oak, cut down no doubt from the surrounding park and very probably buried in the ground for a number of years to season, a very different process from our own, for I can well imagine anyone starting to build it now would want the whole building finished within a year But what is the result of this careful work? The whole is to-day in a very good state of preservation, and no doubt with care bestowed upon it will last for many generations yet. The stonework must have been most carefully selected and manipulated, and all the building, so "fitly framed together," is a monument of good workmanship. It may be said that this was a mansion and so money was *lavished* on it. Well, let us look at another building in the same neighbourhood and built about a century later—the "Holt Almshouses." Although these are only cottages they also exhibit care and thoroughness in building and, comparatively speaking, have withstood the elements as well as the larger Hall. In our ecclesiastical buildings too we see the highest products of the skill of the builder and craftsman. Yet, to-day even our churches and chapels are sometimes flimsily built. Nonconformists are the greater sinners in this respect. A short time ago, speaking at a stone-laying ceremony in connection with the extension of a Congregational church which I was carrying out, an eminent Nonconformist divine adjured architects to abandon their æsthetic designs and costly finishings for churches, and instead to build them to hold as many people and *at as little cost* as possible, a sentiment quite unworthy of the speaker and of the cause for which he was pleading.

For many of the shortcomings in modern work the commercial spirit of the age is responsible—the spirit of gain and money-making. Everything must be turned out "at a price" and in addition the work is required to be done within a stipulated time, often a most unreasonably short one, which makes good lasting work impossible. In buildings like hospitals, clubs or large residences there is a care for health and comfort, as well as good workmanship, which is a credit to those who build them; but in the modern villa of a certain type, and especially in the workmen's dwellings of to-day, the spirit of commercialism is dominant, and, were it not for the restrictions of the local authorities, then things would be bad indeed. The building of houses for the people is a most important department of modern building, for the influence of their surroundings cannot be over-rated. A great writer has said: "I am a part of all that I have met," and if this be true how much more may it be said that one is a part of that in which he continually lives.

Unfortunately the building of workmen's dwellings is for the most part left to unprincipled speculators, who buy a field, drive a street through it, scarcely taking the trouble to strip off the turf, and in an incredibly short time the rows of flat repulsive houses are reared. Badly-built houses are a crime against humanity, and their influence on the men, women and children who inhabit them is most direful; but the jerry-builder is not overburdened with conscience and sacrifices everything to the consideration of cheapness. These houses soon fall into a condition of bad repair and afterwards become mere squalid hovels. Surely the remedy for this state of things is at any rate to some extent in your own hands. If I were the leader in the trade union I would try to induce workmen not to work for a jerry-builder, or if they did, to insist on the work being done in a proper manner. Attention has lately been directed to a "Garden City" scheme, and the benefits which are connected with it can be seen at the great industrial settlement known as "Port Sunlight." The houses in "the village" are *built*, not thrown together, and have the most modern sanitation; there are 230 or 240 houses in the village and about 1,800 workpeople. Each cottage has a bath-room and not one contains fewer than three bedrooms. A similar village has been founded by the Brothers Cadbury at Bournville: and if we cannot start such schemes as these we can at least refrain from having any part in the erection of jerry-built houses which operate in an exactly different direction and instead of promoting the happiness of those who live in them bring a great deal of discomfort and misfortune.

---

* Summary of a paper read before the Birmingham and District Clerk of Works and Builders' Foremen's Association by Albert S. Smith, president of the Birmingham Master-Builders' Association.

New Patents.

These patents are open to opposition until March 15th.

1901.—Heating Greenhouses.—3,695, E. J. JOHNSTONE, Rougham Hall, Bury St. Edmunds. The circulating pipes are placed in or surrounded by a tank of water, which gives off heat evenly and regularly: and also retains the heat for some hours after the fires have gone out.

Brickmaking Machines.—4,772, H. J. LINTOTT Horsham Engineering Works, Horsham, Sussex. This invention relates to a mill for hand-made bricks and its object is to avoid the necessity for employing hand labour to convey the pugged clay from the mill to the moulding table. Thus, the pug-mill is sunk in the ground beside the table so that clay may be tipped into it from a barrow. It is provided with cutters mounted on a horizontal shaft, while at the bottom there is an opening communicating with a trunk containing a spiral, which raises the clay to the table.

Treating Bricks.—10,160. A. J. KEEBLE, Walton House, Park Road, Peterborough. To prevent "scum" the brick or tile, before being dried and fired, is dipped into a solution of glue 25 lbs. dissolved in 20 gals. of water. The colour of the brick is thus kept uniform throughout.

The following specifications were published on Thursday last, and are open to opposition until March 22nd. The names in italics are those of the communicators of the inventions. A summary of the more important of them will be given next week.

1900.—23,461, WAYSS & FREYTAG, method of impregnation and isolation of protecting pipes for underground cables, &c.

1901.—592, GRATH, kilns. 876, STEAD, self-acting opening and closing apparatus for doors. 1,640, RUTNAGUR, water-supply controlling and waste-preventing apparatus. 2,531, HUGHES, cistern valve. 2,613, SNOWDON, kilns. 2,728, HEAP, roofing tiles. 3,412, ADAMS, appliances for operating fanlights, casements, &c. 3,428, PROCTER, chimney tops and ventilators. 3,814, DOMAN, hinges. 3,919, FIDDLER, PURCELL & DURNFORD, picks, axes, hammers, &c. 4,123, HILDRED & R. WAYGOOD & CO., LTD., slack-cable safety gears for electrically-operated lifts, 4,172, BRYANT & WITCOMBE, planes. 4,267. DIXON, self-closing taps. 4,468, CASSELS, stable fittings. 4,749, STEWART, spanners or pipe wrenches. 7,789, STUBBS, scaffold bracket. 7,992, CASE, smoke sewer systems.

8,870, ZACZEK, paper air-pipes for ventilation. 9,158, BROWN, pulley frames for windows. 11,472, STONE, rope clamps 14,306, GARUTI & POMPILI, process of soldering with oxy-hydrogen gas. 17,431, WOOD & BARTLETT, manufacture of woodite. 18,470, MARTIN, window sashes and frames. 22,198, BOULT (*Scherzer*), bridges. 22,314, VON FORELL, apparatus for the preparation of Portland cement from blast-furnace slag or cinder. 22,383, HUGHES (*Larsen & Wong*), pulley block. 23,061, MOATE, locks. 24,475, CARTER, elastic plaster for walls and ceilings.

Enquiries Answered.

The services of a large staff of experts are at the disposal of readers who require information on architectural, constructional or legal matters. Questions should in all cases be addressed to the Editor. The querist's name and address must always be given, not necessarily for publication.

Architect's Charges for Preparing Quantities, &c.

W. H. G. writes: "After preparing the plans, &c., for a small house, I was asked to obtain tenders. I prepared quantities (without the client's orders) and had copies made which were sent to the respective builders. The lowest tender received was £408. This amount being too high, I was able by alterations and deductions to reduce it to £292. Can I lawfully charge for these quantities and copies; if so, to what extent? Also, upon which tender can I claim the usual 2½ per cent. for working drawings, &c.?"

You can claim what is a fair charge, and you are entitled to be paid for the preparation of quantities and plans on the £408, additional for modifying, and the final 2½ per cent. for execution of work upon the £292. You are entitled at least to 2½ per cent. on £408 for plans, 2½ per cent. on this amount for procuring tenders and taking out quantities, and 2½ per cent. on £292 for execution, and extra payment for making deductions. If, however, you were given orders in the first instance not to exceed £300, we do not think you can legitimately claim for more than 6 per cent. on this amount and another 2 per cent. for quantities: 5 per cent. for such a small house is not remunerative.

Bad Draught in Flue.

BIRMINGHAM.—THE JEVON CO. write: "We have fixed a small hot-water boiler with about 9ft. of 5in. cast-iron smoke pipe, carried into a 9in. drain-pipe flue running under a conservatory floor about 40ft., entering a soot chamber covered with stone slab, and turning off nearly at right angles (80 degs.) another 20ft. under ground into a new 9in. by 9in. flue 40ft. high. We cannot get this to draw, and we fear we have made a mistake in laying too large a drain-pipe. Can you suggest a remedy?"

The horizontal part of the flue will of course tend to cool the gases very considerably before they reach the vertical part, besides causing considerable friction, but even then a height of 40ft. ought to cause a perceptible draught, although probably insufficient. The most important thing is to see that there is no leakage whatever of air through any of the joints or connections between the boiler and the highest point of the flue. Changes of sectional area are bad for a flue or for any other conduit for the transmission of fluids or liquids. The 9in. drain-pipe flue instead of 6in. is not the cause of the want of draught, but the great horizontal distance compared with the vertical height. The main points to keep in view are to send the gases hot into the chimney and to let no cold air leak in anywhere. Of course if the chimney can be raised the draught will be improved, presuming that the furnace is so situated that air to feed the fire is readily admitted.

HENRY ADAMS.

Quantity Surveyors' Fees.

SOUTHPORT.—G. H. writes: "What do surveyors usually charge for (1) taking out quantities, (2) measuring up the building, making out extras and omissions and checking accounts?"

(1) For small or difficult works up to £2,000 value, 2½ per cent. For ordinary works from £2,000 to £10,000 1½ per cent.; above this 1 per cent.; lithography extra. (2) For measuring up works for small new buildings and in repairs, including bill of particulars, 2½ per cent., in large new works of plain character 1½ per cent.; in works of small value three guineas per day. For measuring up extras and omissions, 2½ per cent. on amount of extras, 1½ per cent. on omission if involving measurement, and 1 per cent. on omissions if not involving measurement.

Condensation of Moisture.

VINO writes: "A solid concrete floor has been laid 7in. thick of cement and breeze ashes, with a granolithic topping. The ceiling on the underside sweats very much and has done so for more than four months. The cellars have to be kept warm and the heating is done by gas. Directly the gas is lowered and the temperature falls the moisture disappears. Is this condensation, and if so, what can be done to stop it? I do not think any moisture comes from above."

A gas fire produces a large amount of moisture and this will condense on any cold surface. The ventilation requires to be improved. It would be best also to board the ceiling under the open yard with slag-wool in between, as it is an excellent non-conductor.

Width of New Streets.

CAMBERLEY.—F. C. U. writes: "The approach to the six proposed cottages shown on the accompanying plan (not reproduced) is by a 15ft. road in front and a 4ft. passage at the rear. The Model By-laws of the L.G.B. are in force in this district and where a new street is proposed they require the same to be 36ft. wide; and every street not intended as the principal approach to any building, but for the removal of the contents of any privy, ash-pit, &c., to be 16ft. wide. (1) Do existing buildings (which are old) affect the circumstances of the case? (2) Is the owner forming a new street; and if so is the street in accordance with the local by-laws? (3) Do the proposed houses contravene the Buildings in Streets Act, 1888, in relation to the building line?"

(1) The existing buildings do not apparently affect this particular case, so far as regards the new buildings under consideration. (2) Yes; but the proposed new street is not in accordance with the local by-laws. (3) It is considered that the proposed houses do not contravene the Public Health (Buildings in Streets) Act of 1888, 51 & 52 Vict., c. 52, as reasonably interpreted and applied to this particular instance.

T. E. C.

Architectural Lettering.

HASLINGDEN.—BINKS writes: "Kindly name a good book for different styles of lettering suitable for an architect or surveyor when making the headings for large plans?"

"Alphabets, Old and New," by Lewis F. Day (B. T. Batsford, 3s. 6d. nett).

Formulæ and Particulars of Timber.

FROME.—YOUNG ARCHITECT writes: "Please recommend a good pocket-book giving the sizes of timbers for different spans, &c.?"

Hurst's "Architectural Surveyor's Handbook" (E. & F. N. Spon, 4s. nett).

Temple of Eleusis.

NORTHAMPTON.—ARCHITECT writes: "(1) Where can I obtain information concerning the Greek Ionic Temple of Eleusis? (2) In preparing the sheet of drawings of Gothic ornament from the round for the R.I.B.A. Intermediate Examination, must I give one drawing to fill the whole sheet, or could I give half a dozen small ones?"

(1) See p. 93 of our issue of September 5th, 1900. (2) A sheet of drawings of several examples of Gothic ornament is required.

Remedying Dampness in Wall.

LEAMINGTON SPA.—NEWOB writes: "I have been asked to suggest a remedy for damp in the following case. The outer 9in. wall of a dwelling-house absorbs the rain to such an extent that it shows on the inside, making the wallpaper damp and discoloured. The wall is built of ordinary common bricks, and plastered on the inside. Can you suggest a remedy? Something cheap and simple preferred."

You can either render the wall outside with Portland cement; tile or slate it; or coat it with a composition of tar and pitch, applied hot. The last method is cheap but unsightly and requires constant renewal.

Architectural and Surveying Appointments under Government.

DUBLIN.—PERPLEXED writes: "What positions in His Majesty's Service are open to a young architect and surveyor?"

The principal appointments of this nature under Government are those of Assistant Civil Engineer, Admiralty; Assistant Surveyor, Royal Engineers; and Assistant-Surveyor, Admiralty. These are obtained by open competitive examination, particulars of which will be supplied gratis by the Secretary, Civil Service Commissioners, 68, Victoria Street, S.W., who will also supply details of the examination for County Surveyors in Ireland. Appointments under municipal bodies are, as a rule, obtainable only by application, supported by local influence.

Architects' Formulæ.

LONDON, N.—F. G. J. writes: "In an old R.I.B.A. examination paper appears the formula for beams $W = \frac{cbd^2}{l}$ which is referred to as the 'ordinary' formula. Where can I find an explanation of it?"

The formulæ generally used by architects are set out and explained in Hurst's "Architectural Surveyor's Handbook."

White Efflorescence on Brickwork.

KINGSBRIDGE.—T. W. L. writes: "How can I prevent white deposit showing on the face of brickwork (probably due to salt)?"

The white efflorescence is saltpetre, and is due to the bad composition of the cement or lime. When these combine to form insoluble compounds the saltpetre is often produced as a by-product, but this is evidence of bad composition. The clays used in bricks also often contain saltpetre, and effloresce. It can be removed as it appears by applying acids to the surface with a brush.

Board School Buildings.

ILKLEY.—R. F. writes: "Where can I obtain particulars of the accommodation, light, ventilation, &c., required in Board School buildings?"

See a paper on Board Schools read by Mr. T. J. Bailey before the Royal Institute of British Architects on May 29th, 1899, and published in the transactions.

Timber Roof and Cost of School.

LONDON, N.W.—FENLAND writes: "(1) Is the roof shown on the accompanying sketch (not reproduced) suitable for a span of 21ft., the outer walls being 13½in. thick, and the ceiling carried up to the collar? What would be the price per scholar of a mixed school for 170, built in one storey in yellow brick walls, red tile roofs, and 14ft. high to ceiling; wood block floors, walls plastered inside and coloured?"

(1) Yes, the roof would be good enough, but a simpler and cheaper one would answer the purpose quite as well. See Rivington's Building Construction, Vol. I., where sizes of timbers, &c., are given. Straps should be used at all joints. There is no need for a buttress with 13½in. walls. The methods of calculating dimensions and thicknesses of walls and buttresses are given in Allen's, Mitchell's or Rivington's books on Building Construction. (2) We can only give you a very rough approximate cost namely, about 6d. per foot cube, or £7 per scholar.

Masters and Men.

Blackpool and St. Annes Joiners' Strike has been settled after a struggle of fourteen months. The employees have decided to accept the employers' terms of 8½d. per hour, subject to some slight alteration in certain of the rules. The terms of settlement are equivalent to ½d. less per hour than the men were receiving prior to the dispute. In order to provide against any further disruption in the future a conciliation board will be formed, consisting of three representatives of the masters and men, to watch the respective interests.

Bricklaying and Trade-Unionism : L.C.C. Enquiry.—The Finance Committee of the London County Council have instituted enquiries in view of the statements made in "The Times" that the maximum of 400 bricks per day was the recognised limit for dwelling-houses, shops and business premises built by a private contractor; and that the Council's limit was 330 bricks per day. After remarking that no such "limit" has been recognised by the works manager, the Committee say : "We have been furnished with the opinions of several London firms of contractors as to the present and past output of bricklayers employed by them. There is a difference of opinion as to the number of bricks actually laid, but we find a general agreement that the number laid per man per day is considerably less than the corresponding number laid from twelve to fifteen years ago, though it has risen somewhat from the number laid two or three years ago. The officers of the Council whom we have examined are not altogether agreed as to whether the number of bricks laid by men employed in the Works Department is equal to the number laid by bricklayers employed by contractors. Although we have given the matter our careful attention, the difficulty of obtaining accurate and comparable data has prevented us from arriving at any definite conclusion upon the point. We have not been able to obtain detailed information with respect to any of the large works completed by the Department owing to the absence of any details as to the actual cost to the Department of brickwork. We have, however, obtained from the manager of works a rough calculation of the rate of three works recently executed or in course of execution by the Works Department—namely, Perry Vale fire station, Battersea Bridge dwellings and Seymour and Somerset buildings. The manager arrives at his results by dividing the total number of rods of brickwork by the number of hours returned as worked in laying the bricks. We conclude from the figures that, taking into account every class of brickwork found in buildings of the above character, the figure of 330 bricks per man per day is considerably below the number actually laid."

Workmen's Compensation and Wages : Deputation to the Home Secretary.—Replying to a deputation which waited on him last Thursday from the Parliamentary Committee of the Trades Union Congress, Mr. Ritchie said that labour at the present time was in a much more satisfactory condition than it had been. The deputation had really only brought before him two questions. One was the Workmen's Compensation Act, of which it was stated, and he thought with justice, that it should be amended and made more simple and comprehensive. At the same time he contended that nothing should be done that would hamper employers in their business, because it would be injurious not only to them but also to the employed. With regard to the general question of the amendment of the Act, he thought they would be acting on sound lines by resolving not to unduly hurry forward the amendment. The result of his observations might be summed up thus: they acknowledged that there were various points which were unsatisfactorily dealt with; they were carefully watching all these various schemes with a view to bringing forward an amended Bill; and when that Bill was brought forward they would also have to consider the question whether it should be extended to other trades, and if so to what trades. The Parliamentary Committee also asked not only for an enforcement of the existing law, but also for a considerable extension of it. What was known as the fair wages clause did not go to anything like the length which the resolution before him desired it should go, because it was sought to substitute for the fair wages clause a clause saying that payment should not be less than the trades-union rate of wages in the district. He did not think he could hold out any further hope of extension of the existing law in that direction. In such a case as that which had been brought before him, where it was asserted that some men were paid less than others in a district, he suggested that it might be dealt with by a penalty for breach of contract. If a contractor did not carry out the terms of his contract he was liable to be struck off the list of contractors. That would be one of the most drastic clauses, and he should be glad indeed to make a representation to the Treasury in regard to that point, and he felt that the Treasury would readily agree with him.

Engineering Notes.

The Cost of the Trans-Siberian Railway up to date has been approximately £40,000,000. A further sum of £2,000,000 or £3,000,000 will be required to complete it. This gives an average of about £5,000 a kilometre.

St. John's Church, Devizes, has lately been fitted by Messrs. John King, Ltd., engineers, Liverpool, with their "Small Tube" hot-water heating apparatus, employing their economical coil heater with waterway firebars.

The Union Infirmary, Kington, Herefordshire, is being warmed and ventilated by means of Shorland's patent double-fronted Manchester stoves with descending smoke flues, supplied by Messrs. E. H. Shorland & Brother, of Manchester.

A New Bridge at Guildford has been opened across the Wey. The bridge, which has been constructed of iron girders of a span of 70ft., take the place of the old brick and stone structure which collapsed in the flood at Guildford nearly two years ago. It has been built from designs of Mr. J. Webster, M.I.C.E., by Messrs. Fasey & Son, of Leytonstone, the contract price being £5,596.

A Rapid Railway between Glasgow and Edinburgh.—The "Glasgow Evening Citizen" announces an important project for the construction of a railway on the mono-line principle between Edinburgh and Glasgow, similar to the one being made between Liverpool and Manchester. Plans and a mapped route have been submitted to the Board of Trade. The intention is to give a ten-minute service of trains running at a speed of 117 miles per hour, the distance to be done in twenty-five minutes. There will be no intermediate stations.

The Electric Lighting Boards (British Manufacturing Co.), Ltd., announce that as extra accommodation has now been made available at their registered office, 7, Pall Mall, S.W., the counting house has been removed to that address. (Telephone No. 2,412 Gerrard; telegrams: "Elbenborn London"; Code A, B, C, 5th.) The accommodation at No. 9, Grosvenor Mansions will therefore be devoted entirely to sales. The Company also announce the engagement of Mr. H. Brome Tarry, for many years with Messrs. Lucas & Aird, the great contractors, who will act as manager with Mr. Holland (late assistant trade manager of Messrs. Ind Coope & Co.) as general assistant, and Mr. W. G. Haywood as before works superintendent.

The Institution of Civil Engineers held a meeting last Tuesday, Mr. Charles Hawksley, president, in the chair. Four Associate Members were transferred to the class of Members, namely, Messrs. C. S. V. Brown, W. B. MacCabe, R. W. Richards and W. Spinks. The monthly ballot resulted in the election of six Members, namely, Messrs. A. W. H. Casson, H. D. Ellis, J. J. Impett, J. N. Digues la Touche, F. T. Rednall, Prof. G. F. Swain; nineteen Associate Members, namely, Messrs. E. V. Clarke, B.Sc., R. Das, H. D. Dormor, R. W. Hammond, F. J. Jones, C. B. McRitchie, F. A. Molony, J. Mountifield, T. O. Mullings, W. H. Neilson, B.A.I, A. C. H. Palmer, A. C. Rettie, L. Roseveare, T. Sano, R. S. Solomon, H. S. Threlfall, M.Sc., F. J. C. Tyley, R. W. Vawdrey, B.A., and J. Yamaguchi (Brondesbury); and one Associate, viz., J. F. Thallon.

Ventilation of The Central London Railway is to be improved and experiments are now being made.

Utilising the Tides for Electric Lighting.—At Walton-on-the-Naze a scheme is being carried out for utilising the tides in the back-water to generate a current for electrically lighting the town. It is estimated that the tides will develop sufficient power for both public and private lighting.

Mr. Francis Stevenson, M.I.C.E., the late chief engineer of the London and North-Western Railway Company, died recently. He was born on August 27th, 1827. Mr. Stevenson was an ardent lover of nature, with a profound veneration for ancient and historical buildings. When designing new work, whilst he kept in view the principles of reasonable economy, he was careful so to arrange his designs that as far as practicable they should leave undisturbed any prominent or pleasing feature in the vicinity.

"The Electric Passenger Elevator."—This was the title of the paper which Mr. William J. Cooper read before the Institution of Junior Engineers on Friday last, Mr. Percival Marshall presiding. After dealing with the chief features of an ordinary gear the lecturer said that the electric motor and the winding machinery could be erected either at the top or at the bottom of the hoistway. If fixed at the top, one face of the drum could be plumb over the centre of the car, and the other face plumb over the counterbalance weight. Under special circumstances the machinery might be placed at a distance from the hoistway, and the ropes guided over diverting sheaves, but it was obvious however that the fewer sheaves employed, the less would be the wear on the ropes and less by friction. The arrangement of placing the machinery at the top of the hoistway was particularly adapted to the electric elevator, as the current was easily conveyed by the cables to the motor and controller. The lecturer dwelt on the importance of an efficient form of brake. It might be mechanically operated from the switch gear shaft by the controlling rope or by an automatic magnetic solonoid brake, the type now generally adopted. A solonoid and magnet of small dimensions could be made to give a pull of 500lbs. or 600lbs. through ½in. To meet the severe demands of the elevator, motors of a somewhat distinct class had been introduced, constructed so as to need little attention. A comparatively small motor could be used, as in all cases the maximum load was of short duration, the motor standing idle for at least half the time. Shunt motors were self-regulating if the potential was constant, and were now almost invariably adopted, but with about 10 per cent. of series winding added on the field magnets to enable the motor to develop a powerful torque at the moment of starting. Considerable ingenuity had been expended over the starting and controlling switches, the operation of which might be effected in various ways—either by a hand rope, a hand wheel, a lever, or by a push-button device. The last was to be recommended for private houses or places where an attendant was not required, the elevator being operated by the passenger. After referring to automatic safety devices Mr. Cooper said that an electrical locking apparatus should be fitted to all electric elevators, by which all the hoistway doors or gates would remain locked, except when the car itself was in position at the landing, and stationary. The opening of any door was arranged to break the main circuit of the motor, and it was impossible for it to be started again until the gate was shut and locked and the circuit remade. In conclusion the lecturer pointed out that the power or current used in an electric elevator was in direct proportion to the number of persons or load carried, while with one worked hydraulically it was necessary to fill the cylinder with power water whether the load was light or heavy.

A Site for St. Cyprian's Church, Dorset Square, N.W., has now been purchased from Viscount Portman, a condition of the sale being that the church is built and ready for consecration by June 1st, 1904. The architect is Mr. J. N. Comper, of the firm of Messrs. Bucknall & Comper.

BUILDING CONSTRUCTION.

(Continued from p. 405, No. 363.)

77. EDUCATION will not result from reading or hearing facts which do not appease our mental wants. There is no use in our trying to stuff the mental stomach which is not hungry; there is but little good in education, if indeed it can be called education, whose main purpose is the passing of examinations in the subjects crammed. Examination is valuable and necessary, but the assaying of gold does not produce gold, neither does examination produce scholarship. These things, though often repeated, are more often overlooked. The writer is frequently consulted by parents in regard to proposed careers for their sons (usually respecting some department of engineering). The boy who is handy with tools is the most frequent subject. The object of these articles is to take the workman's side of questions of Building Construction to a greater degree than is done in most of the books, in the belief that this is the direction in which it can be taken with the best educational effect. Most of us have opportunities every day of seeing building operations; if these appeal to us, if we are interested in the growth of buildings, and if we observe workmen at work as a growing habit in ourselves, surely there will be little drudgery in reading particulars and details which are the result of the experience and thought of very many other observers. If we are not in the slightest degree interested in constructional work, if we have no desire to stop and look, if we do not notice the variety of stone and brick employed, and if we do not, at least, feel inclined to ask about any material or mode of working which is unfamiliar to us, then we had better have nothing to do with Building Construction classes and try in some other direction for our education. For a boy to be handy with tools is a good sign, but it is not all the evidence —it is indeed only a small part of it; mere handiness, dexterity with tools and neatness in performing a repeated operation, is not a high faculty; the best workman does not invariably make the best foreman. To be able to do good work by the hands of the average workman is a much higher achievement than to do good work with our own hands. Much of this may be beside what it is desired to express. The argument is intended to be in favour of the method herein employed, that is, making use of a building which has actually been constructed and dealing with its parts as they have come together synthetically. Elementary buildings have been dealt with with considerable minuteness. So far as the articles have gone, it has been the writer's plan to block out the article and then send for an intelligent workman of each particular trade and talk it over with him, and after this consultation the article was written out for the printer. This, of course, does not apply to the articles on "Forces applied to Structures." These articles were written because the writer knows that the subject has hitherto been almost totally neglected in Building Construction classes and it is not sufficiently treated in Building Construction text-books. It is a department of mechanics; it was necessary to pick out the parts essential to Building Construction and place them before students of that subject.

In the articles references have been made from time to time to what it was intended to further explain when the same trade was to be dealt with in more "advanced" buildings. If these further explanations do not appear in the few articles which it will be possible for me to further contribute, students will take the references as indicating the method which I think ought to be followed in any new text-book.

78. In Fig. 20 a method of drawing the joints in rings of elliptical arches was used which possibly deserves some particular note. Ellipses may be drawn with great accuracy with a paper trammel, and students are advised to draw ellipses in this way. Consider the ellipse shown in Fig. 111. Its equation, referred to its major and minor axes as axes of co-ordinates, is $\frac{x^2}{a^2}+\frac{y^2}{b^2}=1$. The figure R Q¹ R¹ Q represents the evolute of the ellipse. It is such that every normal, *i.e.*, every right line which

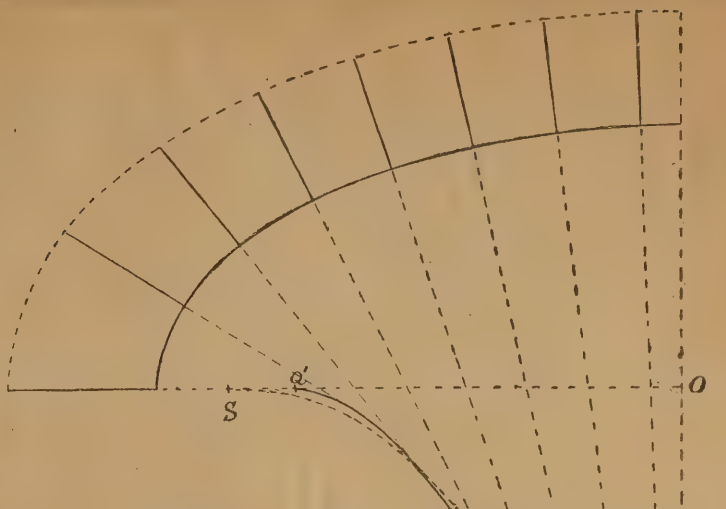


FIG. 112.

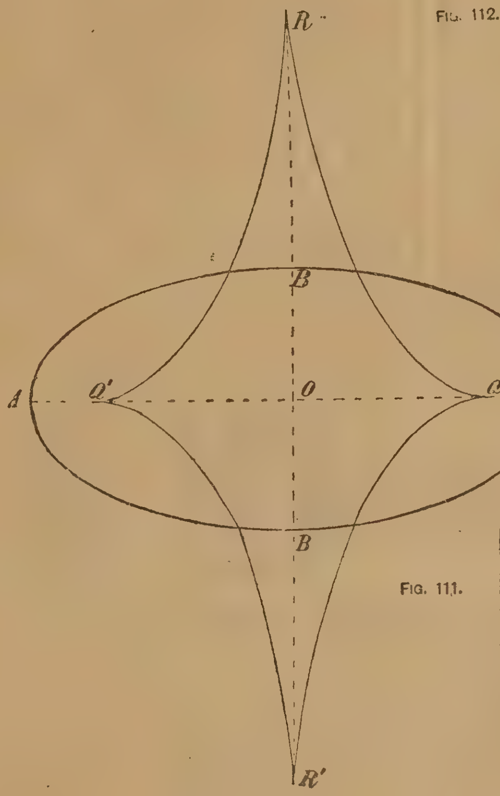

FIG. 111.

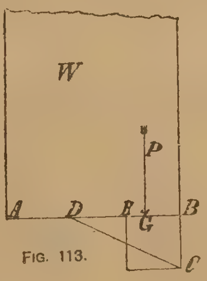

FIG. 113.

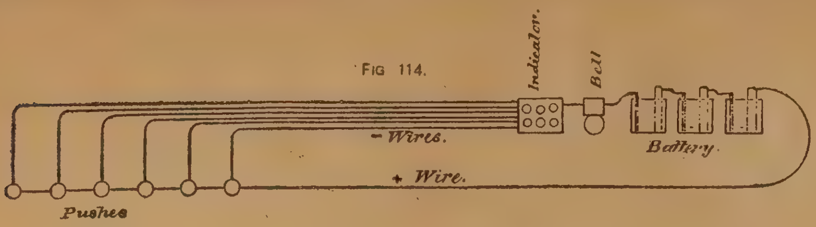
cuts the ellipse at right angles, is a tangent to the evolute. The equation to the evolute is $(ax)^{\frac{2}{3}}+(by)^{\frac{2}{3}}=(a^2-b^2)^{\frac{2}{3}}$. From this equation the four points Q¹, R, A, R¹ are easily found, A Q¹ $= \frac{b^2}{a}$ and B R¹ $\frac{a^2}{b}$. Other points may also be found, but it is not an easy curve to plot. Fig. 112 is intended to compare the curve of the evolute with that of an ellipse whose vertex is at the focus S, where O S is a tangent to it; the line O S is equal to its semi-minor axis and O T is equal to its semi-major axis—$\frac{OS}{OT}=\frac{b}{a}$. For accurate work the curve Q¹ R¹ should be determined by a few points and used for drawing the normals, but it will be generally found sufficient to use the ellipse shown by the dotted line S T as was done in Fig. 20.

79. In regard to the rule as to the centre of pressure not passing outside of the middle-third of the line showing a cross-section of a voussoir joint (paragraph 20), it appears to be taken for granted that this is a rigid rule and that neither in the case of a wall or buttress subject to side thrust nor in arch sheeting must the line of centre of pressure pass outside the middle-third. Suppose Fig. 113 to represent the cross section of a wall resting on a horizontal bed A B. The centre of pressure is at G, and suppose the direction of the pressure to be nearly vertical. Suppose P = pressure per unit of length of wall. Take B C to any scale to represent the pressure per unit of area that the material is calculated to safely bear. Take E so that B C × E B = P, make B D = 2BE; join D C. Now, wherever D may fall between A and B the structure will be safe so long as the point where P meets the joint is not less than $\frac{BD}{3}$ from B. If we consider the *strain* along D B we may conceive the joint at A as gaping very slightly, but the structure will be safe. If D passes to the left of A it shows that the material of the wall would be overstressed with the proposed load.

80. The question of revetement walls has not previously been dealt with. This is not a question that can be settled by mathematics: when it is attempted to so treat it the assumption is made that the material to be retained is homogeneous and that it has a definite angle of repose. Such a condition is rarely met with in practice. No doubt the attempt to calculate the limited question is of value, but each case, where masses of earth have to be retained in undisturbed position, must be dealt with after examining the special conditions very carefully. In some cases it will be found that masses of earth tend to move on "backs" of smooth rock steeply inclined and exert very great pressure on revetement walls. In most cases economy in the wall will result from careful attention to drainage so as to have the material close to the wall dry. If loose stones are available they are

FIG 114.



almost as valuable when well packed between a retaining wall and the bank as if the wall had the additional thickness.

Sufficient openings must be provided to let the water pass through the wall from behind. It should be remembered that the slopes of earth cuttings should be drained by drains which run down the steepest angle of the slope; any cutting across the slope is bad; the surface between the drains may be dressed with a fall to the drains, showing like wide old-fashioned corn ridges. The toe of a retaining wall must have a sufficient hold in the ground to prevent it sliding outwards. Filled earth, as a rule, stands at a slope of 1 to 1, and a wall to retain such earth may be built as calculated to support a wedge whose lowest edge (or point) has a dihedral angle of 22½ degs. The advantage in battering a retaining wall may be suggested by considering the material standing at its natural slope. The wall is needed only as we steepen the slope: in all cases the wall may be built thinner at the top than at the bottom. It is often advisable to step the wall at the back and thus avoid battering it in front. It may require to be built heavier in this way, but some saving (in curved wing walls of bridges and similar works) may result from simplification of the connections with end pillars and abutments, &c., as compared with battered work.

HOUSE-BUILDING (*continued*).

81. The use of electricity for household purposes is now so extended that the constructor of houses cannot afford to ignore the arrangements made necessary for its various uses. There are a few simple things which it is necessary to know about electricity: certainly the student of Building Construction should know this minimum. For domestic purposes electricity rings bells, works telephones, produces light, works ventilation fans, &c., and by some advanced enthusiasts it is used for cooking and warming.

82. *Electric Bells.*—The items in a bell installation are (*a*) the battery, (*b*) the wires, (*c*) the pushes by which a circuit is completed by bringing the two ends of a wire together, (*d*) the bell, (*e*) the indicator. The battery is the place where the electricity is generated or created; the most usual form of battery is called the Leclanché. Each cell consists of four parts, namely, an unglazed cylindrical earthenware pot sealed at the top with black material out of which stands a piece of lead to which a wire may be attached by means of a brass screw; a rod of zinc with a piece of wire soldered on to it; a glass jar in which the pot and rod stand; and the solution of sal ammoniac which is filled into the glass jar and is the means of communication between the conductor inside the pot and the zinc rod. If there are long distances a number of "cells" will be required because the pressure (voltage) is increased by increasing the *number* of cells. If the pushes are numerous—that is, if the call upon the battery is frequent—the cells should be of a large size. The bell is a mechanical arrangement such that when it is included in an electric circuit the bell rings. The "indicator" is a mechanical arrangement for showing to a servant which push is being pressed that is causing the bell to ring. The student should examine these things in an actual installation. Let him note particularly how several cells forming a battery are connected. Let him think of a current of electricity as always making a *complete* circuit: the circuit is complete through the battery, the bell, the indicator. The small gap is at a push: the moment this gap is closed by pressing the push the current flows; the moment the thumb is taken off the current ceases. If there were no liquid in the battery the current could not flow (so-called dry batteries are not quite dry), and if the conducting wires carried along walls, &c., were quite dry and insulated there would be no leakage, that is, there would be no current flowing except when a push is pressed. Now when any current is flowing there is chemical action wherever the current is carried by means of liquid or moisture; in the battery the zinc wastes away: if there is leakage by reason of dampness of walls or otherwise there is a waste of one wire, and it is most important for success in electric-bell fitting that there shall be no corrosion of the wires. In books of instructions for electric-bell fitting this point is not sufficiently emphasised, and it is very important. The ordinary wire supplied for electric bells is not sufficiently protected for most houses. What I will call the positive wire, *i.e.*, the wire which comes from the top of a "porous pot," should be well insulated, and it should be run where there is no risk of damp of any kind getting to it. Fig. 114 is a diagram showing how a bell circuit should be arranged.

83. *Electric Supply.*—Just as for the specifying of arrangements for the supply of gas to a building the architect is not necessarily a chemist, so it is not necessary for him to be an electrician or an electrical engineer to control the electrical fitting of a house for lighting and other purposes. The use of electricity is so common, however, that everybody ought to know its common qualities. Electric supply companies—or the electric authority—put in the "service." It has to be settled where the meter is to be stationed, and just as in a gas service there is a main cock on the street side of the meter so in an electric service there is a main switch of sufficient size to serve for the maximum current which can be demanded at any one time in the house. A switch is a means of connecting and disconnecting conductors—"wires." Suppose the *service* consists of two conductors; it will be found on trial that if the two ends of a lamp filament are connected with them the lamp will glow, and if these wires are carried over the house, lamps whose terminals are attached metallically one to each wire will glow. If instead of putting a lamp across the wires a piece of wire smaller than the service wires is placed across them, this piece of wire will be instantly and violently destroyed by heat, and if the applied piece of wire is thicker than the service wires the service wires will be destroyed, and in either case an electrical man will tell you that you have "shorted" the circuit. It is very undesirable to have a "short" of such a kind as that the permanent wires or cables conveying electricity will be damaged, and to prevent injury of this kind what are called "cut-outs" are made use of; therefore, besides having a main switch on the street side of the meter there is also a main cut-out. A cut-out is essentially a piece of conductor much smaller in section than the conductor in a gap of which it is placed; in the event of, from any accidental short occurring in the house, danger to the service wires the *cut-out* will be destroyed and the connection broken. The cut-out is an automatic switch which breaks the circuit if owing to accident in the house a dangerously large current is set up in the service cables. The essential part of the cut-out is the piece of fine wire, but this piece of wire must be of sufficient length so that when it is burnt out the current will not continue to flow (as it does in an arc lamp) across between two separated points; it must also be mounted so that the heat from its destruction shall not set fire to the building, and it must be easily renewable. The student ought to examine for himself a main switch and cut-out. The reason why an electric current flows from one conductor to another is that there is a difference of pressure or potential between them, and this difference of potential is sometimes called polarity. What is called a "double pole" cut-out is one in which there are two cut-out conductors; that is, mounted on the same porcelain or slate base there are two of these fine pieces of wire, and both of the service wires are brought to the piece of apparatus and they are passed through it by means of these fine wires. This is an extra safe arrangement, and it should always be adopted. There is also a double-pole switch, which is a double switch making and breaking contact at both poles or conductors simultaneously. What is called the quick break of a switch is to prevent what is called arcing. When a break takes place an arc is formed between the parts of the switch, and it continues till the distance between them exceeds the arcing distance; the arc should have as short a duration as possible.

(*To be continued.*)

House at Edgbaston, Birmingham.—This house was built for the architect's own occupation about a year ago. It contains three sitting-rooms, four bedrooms, two attics, bathroom, &c. The site was formerly a gravel pit, and the old banks are now thickly covered with gorse and broom which form a pleasing background for the house when seen from the road. The exterior is treated entirely in rough-cast and the roof is of brindled tiles; the windows are casements and frames. It is a comfortable abode in winter, as all the flues are on internal walls, and thus help to keep the house warm.

HOUSE AT EDGBASTON, BIRMINGHAM. HERBERT T. BUCKLAND, ARCHITECT.

Builders' Notes.

The Weston-Super-Mare Master-Builders' Association held its annual dinner last week, Mr. C. Addicott presiding.

The Bristol Master-Builders' Association held its annual dinner last week. The president, Mr. E. Walters, occupied the chair.

Mr. Edwin O. Sachs, chairman of the British Fire Prevention Committee, has been nominated an Honorary Corresponding Member of the Imperial Federation of Fire Brigades in Austria (Oesterreichischer Feuerwehr - Reichsverband) as a mark of esteem, and similarly the Royal Italian Fire Brigades Association asked Mr. Sachs to accept a similar distinction. The Belgian Fire Federation also recently elected Mr. Sachs to be an Honorary Corresponding Member.

The Wakefield and District Master-Builders' Association held its annual meeting recently, Councillor Judge presiding. Councillor Judge was re-elected president for the ensuing year; Mr. J. Bagnall, Mr. H. Fallas, Mr. G. Crook and Councillor Driver were elected vice-presidents; and the following members were elected on the committee as representatives of the several branches of the trade:—Bricklayers and masons—Messrs. C. S. Denison, E. A. Elvey, J. B. Hesling, J. Higgins and T. Lee; joiners—Messrs. J. W. Atkinson, H. Blackburn, J. E. Bramald and J. Johnson; plasterers—Messrs. J. W. Sanderson and Mr. T. E. Senior; plumbers—Alderman Atkinson and Mr. W. H. Moss; slater—M. E. Rycroft; and painter—Mr. G. R. Parker.

The Brighton Master-Builders' Association held its annual dinner last week, Alderman W. Botting, J.P., presiding, who in replying to the toast of "Continued Success to the Association of Master-Builders" referred to a resolution passed by the National Association of Master-Builders deciding to abolish rules in all workshops throughout the building trade, so that the master should be really the master and the only consideration in engaging workmen should be a fixed wage for certain work. He believed it would be for the benefit of the building trade generally, and also for the workmen, that workshop rules should be done away with, because through them it had become almost impossible for master-builders to carry on under existing conditions. Lately legislation had gone much in their favour, boycotting and picketing being now illegal.

London County Council.—At last week's meeting of the Council the Finance Committee brought up their half-yearly statement of works completed by the Works Department during the half-year ended September 30th, 1901. The statement covered twenty-one estimated works. The final estimate for these works was £103,620, and the actual cost £118,162, being an excess of £14,541. The chief loss was shown on the execution of some drainage works in North Woolwich. The final estimate for this was £47,683, whilst it actually cost £64,398, or £16,714 above the estimate. There were losses on a few of the other works, whilst on thirteen there were savings amounting to £2,434, leaving the balance of loss as stated. Since the creation of the Department in 1893 the works carried out have cost £78,844 above the final estimates. The jobbing works show a small balance of cost below schedule value. In the case of the drainage work in North Woolwich, the Main Drainage Committee brought up a long explanatory report and recommended the Council to pass a vote of £13,000 to cover the extra cost of the work. Mr. Beachcroft said that he had not the slightest hope for the Works Department. He referred to the investigation into the Department held six years ago, and said that the report of the minority, who said that the Department would never be a success when carried on by a board or a committee instead of by the engineer or architect, had been amply justified. With the present facts staring them in the face their best course would be to abandon the Department altogether. He had never read so condemnatory a report on any work as that of their engineer on the North Woolwich drainage. After considerable discussion the amendment to refer the matter back to the Committee was rejected and the excess vote of £13,000 passed.—The Council decided that their resolution of October 15th, 1901, conditionally approving the means of escape in case of fire proposed to be provided in pursuance of section 63 of the London Building Act, 1894, on the top storey of a block of offices known as Finsbury Pavement House, Finsbury Pavement, be modified by the substitution of the words "South Place staircase being shut off from the corridors on all floors by self-closing swing doors of deal, 2in. thick, with the upper panels glazed in small squares with $\frac{1}{4}$in. plate glass, except where there are existing swing doors across the corridors next this staircase" for the words "approaches to the corridors where they adjoin the staircases being fitted on every floor, including the basement floor, with self-closing fire-resisting doors so as to prevent smoke or flame passing into the staircases."

Correspondence.

A Zulu Hut.

To the Editor of The Builders' Journal.

Exeter.

Sir,—It may be interesting to note, in reference to the illustration published in your last issue of two natives building a hut in Zululand, that when on a holiday tour in that country three summers ago I learned that the kraals, as shown, have a working life and an actual existence of from ten to twenty years, after which they have to be rebuilt. I noticed that the homes of the natives in different parts of South Africa are by no means alike in construction. Those of the Zulus—as illustrated—remind one somewhat of the sort of places I have visited in the Arctic regions—the encampments of the Laps. But in Bechuanaland, away more to the north-west of South Africa, the walls around—circular on plan—appear to be made of clay and cow-dung; the whole covered by a thatched roof. That a sense of and an unconscious desire for ornamentation exists in the savage breast is pleasantly illustrated by the many *sgraffito* designs, often of most quaint conception, that appear to have been scratched upon some of these mud walls whilst in their wet state.—Yours truly,

HARRY HEMS.

"Papyrolith" and Cork Paving.

To the Editor of The Builders' Journal.

Town Hall, Ilfracombe.

Sir,—Some time ago a flooring material called "Papyrolith" was brought to my notice. It was made of an asbestos composition of a warm chocolate colour which was to be laid *in situ*. Though I have corresponded with some of the largest builders' merchants in the West of England I have failed to find the address of the firm who make or supply this material, and should feel obliged if any of your readers could furnish me with this information. While on the subject I am desirous of learning the address of a firm making cork-paving in blocks. I understand that the Improved Cork Pavement Co., formerly of 21, St. Mary Axe, E.C., has discontinued business.—Yours truly,

OSWALD M. PROUSE, A.M.I.C.E.

Old London Bridge.

To the Editor of The Builders' Journal.

London, E.C.

Sir,—Those of your readers who were interested in the illustrated article on "Old London" in your last issue may like to know that of the alcove shelters shown in the view of the Southwark end of London Bridge as it stood in 1831 two are preserved and form shelters at the east end of Victoria Park, London. They each bear this inscription: "This alcove, which stood on London Bridge, was presented to Her Majesty by Benjamin Dixon, Esq., J.P., for the use of the public and was placed here by the Right Honorable W. Cowper, First Commissioner of Her Majesty's Works and Public Buildings, 1860."—Yours truly, ARTHUR HARSTON.

Keystones.

Change of Address.—Mr. Frank Windsor, architect and surveyor, has removed to new offices at 9 and 10, Bank Buildings, George Street, Croydon.

A New School at Ellesmere Port has been erected to accommodate 200 boys. The cost of the building, excluding furniture, has been about £1,700. Mr. G. R. Jebb was the architect, and Messrs. E. Griffiths & Co. were the contractors.

The New Oak Chancel Screen in the Church of St. Matthias, Earl's Court, referred to on p. 441 of our last issue, was executed at a cost of £380 by Messrs. Harry Hems & Sons, of Exeter, who also erected a sculptured oak pulpit in the church a few months ago.

At Queen Anne's School, Caversham, a new wing has been erected. It contains a residence for the head mistress and an assistant mistress, two pupils' rooms, dormitories for thirty pupils arranged in cubicles, three bathrooms, lavatories and offices, and in the basement are fireproof cellars for hot-water furnace, heating apparatus, &c. This wing is connected to the main building by a wide corridor. Messrs. G. Lewis & Brother, of Reading, were the contractors, and Mr. J. Osborne Smith, F.R.I.B.A., of Westminster, was the architect.

A Memorial to Ruskin in Westminster Abbey was unveiled by Mrs. Arthur Severn on Saturday last. It takes the form of a bronze medallion by the late Mr. Onslow Ford, R.A., and occupies a position in the Poets' Corner, immediately above the bust of Sir Walter Scott. The medallion has cost £263 10s. and its fixing £5: but there is the most startling addition of "Westminster Abbey fees—£201 1s."! Ruskin was born on February 8th, 1819, at 54, Hunter Street, Brunswick Square, W.C. (now marked by a Society of Arts plaque), and died at Coniston on January 20th, 1900.

A Memorial at Addiscombe, Croydon, is being erected to the brave men who were trained for Indian service at the old East India Company's Military School for Officers. The Institution sent out 3,000 men between the years 1809 and 1861 to fight the battles of their country. The memorial takes the form of a church, on a site near the spot where the Cadets' Training School formerly stood. It was dismantled when need for it ceased, owing to the Imperial Government taking over the defence of India and its general administration. The church, according to the completed design, will cost £11,000. The present scheme embodies a substantial portion, involving an expense of £6,600.

New Parochial Buildings for St. Stephen's, Newcastle, have been erected in Tulloch Street. Mr. S. D. Robbins, architect, Newcastle, designed the building, which is Gothic in style; it has been erected by Messrs. T. & R. Lamb. The site is 92ft. long and 70ft. wide. The principal room on the ground floor is the parish hall, in which there is seating accommodation for about 600 persons. Adjoining are classrooms and a committee-room, &c. On the mezzanine upper floor there are also classrooms. The wood flooring has been provided by the Acme Flooring Company, of London; the plasterwork by Messrs. W. B. Wilkinson & Co., of Newcastle; and the steam-heating by Messrs. Ashwell & Nesbit, of London. Mr. Michael Stevenson acted as clerk of the works.

A City Churchyard.—The alterations in connection with the churchyard at St. Andrew-by-the-Wardrobe, which is situated next to the Bible Society's premises in Queen Victoria Street, E.C., have now been completed. In place of the high and ugly blank wall, new wrought-iron railings and stone piers with carved vases have been erected. The wrought-iron gates are given by Mrs. Banister Fletcher in memory of her late husband, who was churchwarden. The churchyard has been laid out in terraces and covered with turf, exposing one of the best of Wren's churches to public view, and adding another green spot to London's dingy exterior. The work has been designed and carried out under the superintendence of the architects, Messrs. Banister Fletcher & Sons.

A New Fish Market and Coaling Stage at Swansea has been erected at the Prince of Wales's Dock at a cost of £20,000.

The R.I.B.A. Annual Dinner, 1902, will be held in the Whitehall Rooms of the Hotel Métropole on Thursday, June 19th.

Isolating the National Gallery.—It is expected that the premises needed for the isolation of the National Gallery will be demolished this summer.

A New Public Library at Hampstead has been opened at Cotleigh Road by the Hampstead Borough Council to replace a temporary one at Priory Road.

Sculpture for a French Bridge.—The sculptor, Corneille Theunissen, who has been lately decorated with the Cross of the Légion d'Honneur, is engaged in the creation of four allegorical figures destined to ornament the new bridge over the Somme at the entrance of the old town of Saint Quentin.

A New Infirmary and Tramp Wards at Solihull, part of the scheme proposed a few years ago for the reconstruction of the workhouse, has been opened. The work has been carried out by Messrs. W. & T. Thompson, builders, Solihull, to the designs of Mr. W. H. Ward, architect, of Birmingham.

A New Church at Camberley is to be erected from designs by Mr. W. D. Caröe. At present it is intended to erect the nave only, to seat 300 persons, at a cost of £2,200. Over £3,000 additional will be required to complete the entire structure, when accommodation will be provided for 500 persons.

An Architectural Competition for Students.—The Alexander Thomson Travelling Studentship, value £60, will be held this year for the ninth time. It is a triennial one. The drawings are to be sent in by Friday, December 26th. The programme consists of (1) restoration of the Tower of the Winds at Athens, and (2) design for a building to accommodate the Fine Art Department of a University. The Trustees have resolved to offer a second prize of £20 should the quality of the work and the number of competitors warrant this. Competitors must be between eighteen and twenty-five years of age, natives of and resident within the United Kingdom. Detailed programme and conditions may be had on application to Mr. C. J. Maclean, 115, St. Vincent Street, Glasgow.

A Memorial to the late Lord Armstrong is proposed to be erected in Newcastle-on-Tyne and is to include a portrait statue. The committee invite designs for the memorial, which must be suited to the site and climatic conditions of the city. The statue itself, it is suggested, should be of bronze and form the most prominent feature. Competitors must be prepared to carry out the memorial, including its erection and accessories, at a cost of about £5,000. Mr. Alfred Gilbert, R.A., will act as assessor or adviser, Three competitors at least will be asked to carry their designs further, and they will each receive an honorarium of £25. The second and third best designs will receive £75 and £50 respectively. All designs should be ready by June 1st. Further particulars can be obtained from Mr. Herbert J. Richardson, 67, Westgate Road, Newcastle-on-Tyne.

Partnerships Dissolved.—The partnership between Messrs. Albert Edward Pridmore and Andrew Whitford Anderson, carrying on business as architects and surveyors, at 28, High Street, Watford, Herts., under the style or firm of Pridmore & Anderson, has been dissolved from December 31st last. Mr. Albert Edward Pridmore will henceforth carry on practice at "Cheylesmore," Park Road, Watford aforesaid, and at 2, Broad Street Buildings, London, E.C., and Mr. Andrew Whitford Anderson at 28, High Street, Watford.—The partnership between Mr. John Henry Burton, of Warrenlea, in the county of Lancaster, and Mr. Joseph Ashton Percival, of Oldham Road, both of Ashton-under-Lyne, practising as architects and surveyors, at Ashton-under-Lyne, under the style or firm of "J. H. Burton & J. A. Percival," was dissolved from December 20th last, by the death of Mr. John Henry Burton; and in future the business will be carried on by Mr. Joseph Ashton Percival under the style of "J. H. Burton & J. A. Percival."

The R.I.B.A. Annual Exhibition of Designs and Drawings, held from January 14th to 25th last at the Alpine Club, Savile Row, was visited by nearly a thousand persons.

A Statue of Shakespeare is proposed to be erected in Rome by the side of those of Goethe and Dante in token of gratitude to Great Britain for preserving the Italian tongue in Malta.

A New Methodist Chapel at Highbury Vale, Bulwell, has been erected at the junction of Clarges Street and Broomhill Road. Messrs. Herbert Ingham & William Pipkins, of Basford, were the contractors, and Mr. J. R. Swift, of Arnold, was the architect.

The Coronation Decorations.—We are asked to announce that His Majesty the King has been pleased to accept a copy of the current issue of THE ARCHITECTURAL REVIEW containing the coloured scheme of decoration for the Coronation route suggested by Mr. Selwyn Image.

A New Station of the Metropolitan Fire Brigade has been opened in West End Lane, Hampstead. The new station has been erected at an outlay of between £11,000 and £12,000, exclusive of the cost of the site. It is one of the four new stations which have been completed in the outer fire circle of London. All the latest improvements have been introduced; electric light has also been provided. An important feature of the station is the increased accommodation for the staff, provision having been made for housing twelve men and their families.

The Extension of Paris.—The levelling of that portion of the fortifications of Paris which extends from the Seine at Auteuil to Saint Denis, and which has been talked of so long, seems to be on the point of realisation. By it the city of Paris will be increased by the addition to its area of the Bois de Boulogne, and all the various suburban districts existing between the present City walls and the Seine. The value of the wall and moat round the city as an effectual means of defence is contested by high military experts.

"Some Aspects of Art and of Modern Life" was the title of a lecture by Mr. Selwyn Image at the Working Men's College last Saturday. Individual buildings, he said, however fine were not enough to compensate for the fact that our ordinary architects and builders were deficient in the qualities necessary to the construction of a building artistically decent, let alone fine. The recent modernizing of the houses in Bloomsbury Square and the transformation of Russell Square had destroyed the character and proportions of house fronts, which, if plain, had had artistic quality.

A New Reredos in Downend Church is being erected as a memorial to the late Mrs. Skelton. It has been designed and executed in the studio of Mr. Frank Bell, in College Green, Bristol. The reredos has been kept in harmony with its surroundings. The design consists of two flat panelled wings flanking an elaborate and buttressed centre-piece, which rises above them, and contains two foliated panels and the arched head of the central recess. A bold enriched moulding, supporting a pierced cresting, surmounts the whole. Late Gothic is the general style of the work, which is executed in specially-selected oak, oiled, but left uncoloured.

The Society for the Preservation of "Vieux Paris" continues its efforts to save for posterity as many relics of the past as possible. Very soon there will be little left of the old city. The latest treasure rescued from the destroyer is the ancient Hôtel des Miramionnes, 47, Quai de la Tournelle. It is one of the most picturesque houses on either side of the river, and contains a fine staircase, quaint rafters and windows, while on the ground floor there is a seventeenth-century chapel which has guarded its rare woodwork and monotone paintings. The fine garden was designed by Le Notre, and the trees date from the time of Louis XIV. The hotel was built for a convent, but the Revolution came and the sisters were turned out, the house afterwards being used as a hospital dispensary. The building in all likelihood will be transformed into a museum.

New Companies.

Alteryn Brick, Tile and Terra-cotta Works, Ltd.

Registered to acquire the business of a brick, tile and terra-cotta manufacturer, now carried on by Jesse Davies at Alteryn, near Newport, Monmouth; and to carry on the business of manufacturers and sellers of bricks, tiles, pipes, terra-cotta, pottery, earthenware, enamelled glazed goods, sanitary ware, &c. Capital £3,000 in £1 shares. The first directors are T. Goldsworthy, Henry P. Davies, Edgar Williams and Jesse Davies (managing director). Registered office: Bangor Wharf, Newport, Monmouth.

City and Counties Estates, Ltd.

Registered to acquire lands, buildings and property of whatever tenure, in the City of London or elsewhere, and to develop, deal with and turn to account the same in such manner as the company shall see fit; as builders and contractors; to advance money to builders and contractors, tenants and others. Capital £30,000 in £1 shares.

The Clyde Quarries, Ltd.

Registered to carry on the business of quarry-masters. Capital £10,000 in £1 shares. Registered office: 37, Church Street, Dumbarton.

T. Emlyn Jones, Ltd.

Registered to adopt an agreement made with T. E. Jones for the acquisition of the business carried on by him at Glebe Street, Penarth, and to carry on the business of general and furnishing ironmongers; as plumbers, gasfitters, bell-hangers, electricians, electrical engineers, general house furnishers, merchants and contractors, Capital £15,000 in £1 shares. Registered office: 30, Moorgate Street, E.C.

Empire Enamel Co., Ltd.

Registered to acquire the business of the Empire Enamel Co. as carried on at 101, Redcross Street, Southwark. Capital £6,000 in £1 shares. The directors are E. J. Crosier, J. Dixon and S. Wilkinson. Registered office: 101, Redcross Street, Southwark.

Fal River China-clay Co., Ltd.

Registered to adopt an agreement with A. H. Moore and others for the acquisition of certain patents, and, generally, to carry on business as manufacturers of and dealers in bricks, tiles, china, stone, glass, earthenware, porcelain and other products. Capital £30,000 in £1 shares. The directors are J. H. Calvert, F. R. Andrews, W. A. Dow, H. A. H. Moore and H. P. Calvert.

Foxon, Haggie & Co., Ltd.

Registered to acquire the business carried on by Foxon, Robinson & Co., Ltd., at the Baltic Sawmills, Sheffield. Capital £30,000 in £10 shares. The directors are J. D. Foxon, J. D. Haggie and C. S. Merrill. Registered office: Baltic Sawmills, Colver Road, Sheffield.

W. Franklin & Sons, Ltd.

Registered to acquire the business carried on by W. Franklin, builder and contractor, at Devonshire Place, Newcastle-on-Tyne. Capital £3,000 in £1 shares. The directors are W. Franklin, W. W. Franklin and F. Franklin.

Gas Extension Contracting Co., Ltd.

Registered to adopt a certain agreement for the acquisition of certain inventions relating to (1) a new atmospheric gas burner which can be used in various ways, (2) a new stove in which the same is used, and (3) a new apparatus for the consuming of smoke from coal fires by the use of gas. Capital £6,000 in £1 shares. The first directors are T. R. E. Branston (managing director) and Colonel A. F. Budden.

C. Harrison & Co., Ltd.

Registered to acquire as a going concern and carry on the business of sand and gravel merchants and brick and tile makers at the Merrill's Bridge Brick Yard, West Street, Crewe, Chester, as C. Harrison & Co.; and to carry on business as stone merchants and masons, general merchants, dealers in slates, timber, hardware and all kinds of building materials, and any other business which can be carried on in connection with the above. Capital £2,500 in £1 shares. Registered office: Merrill's Bridge Brick Yard, West Street, Crewe, Cheshire.

Institute of Sanitary Engineers.

Registered with 100 members, each liable for the sum of £2 in the event of winding up. The directors are H. Dove and James Farley.

International Incandescent Light Co., Ltd.

Registered to carry on the business of dealers, makers and merchants of all kinds of accessories for incandescent light, and to acquire the business, property and liabilities of any persons carrying on a similar business. Capital £1,000 in £1 shares. The first director is Charles Welsh. Registered office: 13, Basinghall Street, E.C.

Charles Lathe & Co., Ltd.

Registered to acquire from Charles Lathe the business carried on by him at the Moat Foundry, Summerhill, Tipton, Staffordshire, and to carry on the business of a range, grate and stove manufacturer, makers of grills, mantels, overmantels, tailors' stoves, ovens, &c. Capital £15,000 in £1 shares. The first directors are C. Lathe, A. Lathe and C. E. Lathe. Registered office: 66, Upper Church Lane, Summerhill, Tipton, Staffordshire.

MacLeish, Morrison & Co., Ltd.

Registered to acquire and carry on the business of sanitary engineering of James MacLeish, Mill Street, Perth. Capital £15,000 in £1 shares.

Merton Park Estate Co., Ltd.

Registered to acquire, deal in and with any lands, estates, real or personal property, by laying-out and preparing the same for building purposes, building thereon, planting, paving, draining, farming, cultivating and to advance money to builders, contractors, &c.; to erect clubs, hotels, gas and water works, drainage systems, sewage farms; also as builders and contractors, decorators and merchants of and dealers in stone, sand, lime, bricks, timber, hardware and other building requisites, brick, tile and terra-cotta makers, &c. Capital £175,000 in £1 shares. The first directors are J. Innes, W. E. R. Innes and F. G. Courthope.

Moss & Plumb, Ltd.

Registered to acquire the business carried on by W. Moss & A. Plumb at Hucknall Torkard, Notts, and to carry on the business of timber merchants builders and contractors and dealers in building materials, sawmill proprietors and quarry owners, manufacturers of bricks, tiles, pipes, pottery and earthenware, and as carpenters, joiners, paviors and manufacturers of and dealers in artificial stone. Capital £7,000 in £1 shares. Registered office: Papplewick Lane, Hucknall Torkard.

Norfolk Stone Co., Ltd.

Registered to acquire certain patents relating to the manufacture of stone, marble, cement, bricks, pavement, artificial stone, &c., from A. Crundall. Capital £20,000 in £1 shares.

William Oliver & Sons, Ltd.

Registered to acquire the business of timber and fancy wood merchants now carried on by Thomas Oliver as William Oliver & Sons; and to carry on business as merchants of and dealers in wainscot, mahogany, hardwood, fancy-wood veneer and timber; as sawyers and sawmill proprietors, cabinetmakers, joiners, carpenters, woodworkers, packing-case and box makers, makers of and dealers in fittings, fixtures and furniture of every kind, &c. Capital £100,500 in 20,000 £5 preference and 10,000 1s. ordinary shares. The directors are T. Oliver (chairman), E. T. Oliver, J. E. Oliver, D. W. Oliver, H. M. Oliver and S. Oliver. Registered office: 120, Bunhill Row, E.C

Southern & Nephew, Ltd.

Registered to acquire the business carried on at the Collier Street Sawmills, Knott Mills, Manchester, by R. W. Southern & Nephew, and at the Ellesmere Street Sawmills, Hulme, Manchester, as the Ellesmere Street Sawmill Co., and to carry on business as timber merchants, sawyers, packing-case makers, dealers in woodwork of every kind for builders and contractors; as decorators, painters, plumbers, joiners, glaziers' merchants, dealers in building materials, &c. Capital £30,000 in £1 shares. The directors are R. W. Southern (governing director), G. L. Darwent, S. Lill and J. Lill. Registered office: The Collier Street Sawmills, Knott Mill, Manchester.

St. Margaret's Bay Preservation and Development Co., Ltd.

Registered to purchase on lease or otherwise lands and buildings at St. Margaret's Bay, and to erect or construct in and about St. Margaret's Bay breakwaters, groynes, sea walls, and other works and erections. Capital £2,000 in £25 shares. The directors are H. J. Bakewell, R. C. Darwall and W. H. E. Thornthwaite. Registered office: Fuerteventura, St. Margaret's Bay, near Dover.

Tabor, Trego & Co. (1902), Ltd.

Registered to acquire the business carried on by Tabor, Trego & Co., Ltd., at 42, New Broad Street, London, and at Bow Common, Middlesex, and generally to carry on the business of varnish, japan and colour manufacturers. Capital £87,500 in 80,000 preference shares of £1 each and 150,000 ordinary shares of 1s. each. Registered office: 42, New Broad Street.

George Townend & Son, Ltd.

Registered to acquire the business of cabinet makers, carpenters, joiners, builders, contractors, and painters and decorators as carried on at Halifax, Yorkshire, by David Hanson & Co., Ltd., as George Townend & Son. Capital £10,000 in £1 shares. The directors are D. Hanson, A. Hind, J. Baxter, P. M. Granger and R. Merrall. Registered office: Green Lane, Halifax, Yorkshire.

Unlimited, Ltd.

Registered to carry on the business of a land development company; as builders and contractors, auctioneers and surveyors, decorators, stone merchants, dealers in sand, lime, brick, timber and hardware. Capital £10,000 in £1 shares.

Wear and Portland Cement Co., Ltd.

Registered to carry on business as cement makers as carried on by Mattison & Chapman, and to carry on the business of manufacturers of and dealers in cement, clay, chalk, timber, coal, &c. Capital £25,000 in £10 shares. The directors are H. Webster, W. Sewell, J. Short and R. Thompson.

Surveying and Sanitary Notes.

Safety "Islands."—The Municipal Art Society of New York is holding up London as a model for the Municipal Government to follow in establishing safety "islands" in the middle of streets for the convenience of pedestrians. In order to convert public opinion the society intends to erect such an "island" in one of the busiest parts of the town, and hopes by this means to compel the municipality to cause their construction all over the city.

Sanitary Inspectors' Examination.—The following candidates have passed the recent examination for sanitary inspectors under the Public Health (London) Act, 1891:—Mr. G. W. Adkins, Miss F. A. Baker, Miss M. E. Bibby, Miss H. M. E. Blackwell, Mr. S. T. Bocock, Miss J. J. Brown, Miss M. R. Burrows, Miss A. I. Cocksedge, Miss F. B. M. Ellis, Miss H. F. Ensor, Miss L. L. Ferard, Miss M. F. Hardcastle, Mr. P. A. Heath, Mr. S. R. Henderson, Miss O. C. M. Iles, Miss A. L. Jeffrey, Mr. W. C. Kelland, Miss G. Leaney, Miss F. N. F. Lovibond, Mr. G. Peverett, Mr. W. Rousell, Mr. W. J. Smith, Miss X. C. Turner and Miss I. D. Tyas.

The Special Annual Issue of "The Surveyor," dated January 31st, is a remarkably good one. It contains an interesting review of Municipal Engineering in 1901, dealing with municipal electrical undertakings, water supply, refuse destruction and utilization, sewage treatment, and streets and roads. A useful article on "The legal precedents of 1901 in relation to Municipal Engineering" is contributed by Mr. J. B. Reignier Conder, solicitor, and there is another on the legislation of 1901 in connection with this branch of engineering. There is an illustrated article on the Eastbourne Pier Enlargement and New Pavilion, but perhaps the most admirable feature is the forecast of municipal works projected by local authorities for 1902. There are many other items of interest in the number, which is published by the St. Bride's Press, Ltd, 24, Bride Lane, E.C. The price is 3d.

The Board of Trade Journal.

The Official Organ of the Board of Trade. Published Weekly, ONE PENNY.

Edited by the Commercial Department of His Majesty's Board of Trade.

Contains each week information on Openings for British Trade, Trade of Great Britain, the Colonies, and Foreign Countries, Tariff Charges throughout the World, &c., &c., and various Trade Notes of importance to all Merchants, Manufacturers, and Shippers.

THE TIMES says:—"Everything, small or great, that concerns trade and traders, comes alike within its scope. There is hardly one of its chapters that might not be expanded into a volume, so compressed, so wide sought, and so miscellaneous is the varied information which it conveys. Its statistical tables and its extracts from consular reports abound in interesting facts. It tells us something of the contents of a dozen recent Blue Books, each of them as bulky as itself. Nothing, indeed, comes amiss to it which by any possibility or stretch of language can be included under its comprehensive title."

THE MORNING POST says:—"It is, as its many readers are aware, a record of the recent movements and present position of British and Foreign Trade, compiled from reliable sources, and is a very valuable, if not indispensable, publication to Merchants and others engaged in Commerce."

All Applications for the Insertion of Advertisements in this Journal must be addressed—
